YANG Data Models for the Port Control Protocol (PCP)
draft-boucadair-pcp-yang-04

Abstract

This document defines YANG data models for the Port Control Protocol (PCP), including PCP client, PCP server, PCP proxy, and Universal Plug and Play (UPnP) Internet Gateway Device - Port Control Protocol Interworking Function.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at http://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on November 17, 2017.

1. Introduction

This document defines a data model for the Port Control Protocol (PCP, [RFC6887]) using the YANG data modeling language [RFC6020]. The following functional elements are in scope:

- PCP client [RFC6887].
- PCP server [RFC6887].
- PCP proxy [RFC7648].
- Universal Plug and Play (UPnP) Internet Gateway Device - Port Control Protocol Interworking Function (UPnP IGD–PCP IWF) [RFC6970].

In addition to the base features defined in [RFC6887], this document covers the following capabilities:
In conformance with [RFC7291] and [RFC7488], this document assumes that multiple PCP servers may be configured to a PCP client, PCP proxy, or UPnP IGD-PCP IWF; each server is defined by a list of IP addresses.

This document follows the guidelines of [RFC6087].

This document uses the common YANG types defined in [RFC6991].

This document does not allow to manage advanced PCP authentication features [RFC7652].

1.1. Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119].

This document makes use of the terms defined in [RFC6887], [RFC7648], [RFC6970], and [RFC6970].

The terminology for describing YANG data models is defined in [RFC6020].

1.2. Tree Diagrams

The meaning of the symbols in these diagrams is as follows:

- Brackets "[" and "]" enclose list keys.
- Curly braces "{" and "}" contain names of optional features that make the corresponding node conditional.
- Abbreviations before data node names: "rw" means configuration (read-write), "ro" state data (read-only).
- Symbols after data node names: "?" means an optional node, "!*" a container with presence, and "*" denotes a "list" or "leaf-list".
- Parentheses enclose choice and case nodes, and case nodes are also marked with a colon (":").
Ellipsis ("...") stands for contents of subtrees that are not shown.

1.3. IP Address Format

Following the rationale defined in Section 5 of [RFC6887], this document uses IPv4-mapped IPv6 addresses to encode IPv4 addresses.

The all-zeros IPv6 address are expressed as (::).

The all-zeros IPv4 address is expressed by 80 bits of zeros, 16 bits of ones, and 32 bits of zeros (::ffff:0:0).

2. Overview of the PCP Data Models

The following sub-sections provide an overview of the PCP data models.

2.1. Common PCP

Common PCP YANG data model groups a set of common definitions that are used in all PCP modules.

2.2. PCP Client

Figure 1 depicts the YANG data model for the PCP client.

  description
  "The subscriber-mask is an integer that indicates the length of significant bits to be applied on the source IPv6 address (internal side) to identify unambiguously a CPE.

  Subscriber-mask is a system-wide configuration parameter that is used to enforce generic per-subscriber policies (e.g., port-quota).

  Applying these generic policies does not require configuring every subscriber’s prefix."
Example: suppose the 2001:db8:100:100::/56 prefix is assigned to a DS-Lite enabled CPE. Suppose also that the 2001:db8:100:100::1 is the IPv6 address used by the client that resides in that CPE. When the server receives a packet from this client, the server applies the subscriber-mask (e.g., 56) on the source IPv6 address to compute the associated prefix for this client (that is 2001:db8:100:100::/56). Then, the server enforces policies based on that prefix (2001:db8:100:100::/56), not on the exact source IPv6 address.

    The client requests a certain lifetime, and the server
    responds with the assigned lifetime.

    The server may grant a lifetime smaller or larger than
    the requested lifetime.

    The minimum value should be 120 seconds.

    The maximum value should be the remaining
    lifetime of the IP address assigned to
    the PCP client if that information is available,
    or half the lifetime of IP address
    assignments, or 24 hours.

    Excessively long lifetimes can cause consumption
    of ports even if the internal host is no longer
    interested in receiving the traffic or is no
    longer connected to the network.
    (Section 15 [RFC6877]).";

Security Considerations

The YANG module defined in this memo is designed to be accessed via the NETCONF protocol [RFC6241]. The lowest NETCONF layer is the secure transport layer and the support of SSH is mandatory to implement secure transport [RFC6242]. The NETCONF access control model [RFC6536] provides means to restrict access for particular NETCONF users to a pre-configured subset of all available NETCONF protocol operations and contents.

There is a number of data nodes defined in the YANG module which can, be created, modified and deleted (i.e., config true, which is the default). These data nodes may be considered sensitive or vulnerable in some network environments. Write operations (e.g., edit-config) applied to these data nodes without proper protection can negatively affect network operations. In particular, configuring a fake PCP server may be used to redirect the traffic from a PCP client to an illegitimate server.

IANA Considerations

This document requests IANA to register the following URIs in the "IETF XML Registry" [RFC3688]:

---

4. Security Considerations

The YANG module defined in this memo is designed to be accessed via the NETCONF protocol [RFC6241]. The lowest NETCONF layer is the secure transport layer and the support of SSH is mandatory to implement secure transport [RFC6242]. The NETCONF access control model [RFC6536] provides means to restrict access for particular NETCONF users to a pre-configured subset of all available NETCONF protocol operations and contents.

There is a number of data nodes defined in the YANG module which can, be created, modified and deleted (i.e., config true, which is the default). These data nodes may be considered sensitive or vulnerable in some network environments. Write operations (e.g., edit-config) applied to these data nodes without proper protection can negatively affect network operations. In particular, configuring a fake PCP server may be used to redirect the traffic from a PCP client to an illegitimate server.

5. IANA Considerations
