Generalized Network Control Automation YANG Model
draft-bryskin-netconf-automation-yang-03

Abstract

This document describes a YANG data model for the Generalized Network Control Automation (GNCA), aimed to define an abstract and uniform semantics for NETCONF/YANG scripts in the form of Event-Condition-Action (ECA) containers.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at https://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on January 6, 2020.

1. Introduction

NETCONF/YANG has proved to be very successful in facilitating interactive network control paradigm, in which a network control application (controller) requests the network server to perform certain (re-)configurations, then, retrieves network states of interest, then asks for more (re-)configurations and so forth. This said, there are multiple use cases that require stringing network configuration requests together with conditioning their order of execution based on certain events detected in the network, as well as current, historical or predicted network states, and pushing such request batches/scripts to the network server in order to control the network close loop automation processes. The Generalized Network Control Automation (GNCA) YANG model introduced by this document defines an abstract and uniform semantics of such NETCONF/YANG scripts in the form of Event-Condition-Action (ECA) containers.
2. Purpose

The purpose of the Generalized Network Control Automation (GNCA) YANG model is to enable an environment allowing for manipulation of close loop network automation via configuration of abstract Event-Condition-Action (ECA) scripts. The model defines the semantics of said scripts; however, how the scripts are actually implemented by the server is not governed by the model. The server may, for example, based on pushed ECA configuration, generate and execute server specific scripts. How this is done is outside of the scope of this document.

Although not all event response behaviors could be delegated to the network server, there are many circumstances where it is highly desirable. For example:

a. Reaction to many network events is well understood and does not require additional information (such as broader or higher level network view or analytics input);

b. It is often imperative for the network to start acting as quickly as the event is detected. In other words, there might simply be no time for the network-controller communication;

c. A paradigm in which a controller micro-manages every network behavior does not scale. Simply put, there are always things that the network has to do autonomously (i.e. when the controller is not looking), which does not mean that the controller should have no say as to how said things need to be done;

d. Numerous important use cases and applications can benefit from ability to define in an abstract and uniformly way a programmable logic in one place (e.g. on the controller) and execute it someplace else (e.g. on the server).

The main objective of the GNCA is to generalize the ECA network control style, so that it could be applied to arbitrary network events/conditions and manipulate network auto-control of large variety of network resources. Such a generalization would allow, for example, conveying to the network a coherent/ordered/prioritized behavior for recovering from a network failure or failures affecting simultaneously multiple services, instruct the network how to fight rapidly developing congestions, what to do when power outage is detected and so forth. In fact, it could be argued that without some sort of close loop network control automation hierarchical network control realistically could not be achieved.
The GNCA YANG model could be also thought of as an attempt to generalize the smart filter subscription machinery by stating that sending a notification is one of possibly multiple actions that network could perform reacting to the specified smart trigger. According to "Smart filters for Push Updates - Problem Statement" [I-D.clemm-netconf-push-smart-filters-ps]:

"They [smart filters] are also useful for network automation, in which automated actions are automatically triggered based on when certain events in the network occur while certain conditions hold. A YANG-Push subscription with a smart filter can in effect act as a source for such events. Combined with an optional check for a condition when an event is observed, this can serve as the basis of action."

In a nutshell GNCA facilitates an environment in which the network automation logic could be defined in a form of ECA scripts by a client, pushed to the network before the events of interest happen, and executed by the network after the events are detected.

Finally, according to the smart filters problem statement, the following smart filters will be considered:

"o Filters that involve freely programmable logic"

ECA scripts could serve as a vehicle to associate with a smart filter a complex freely programmable logic to detect the event of interest in the first place.

3. GNCA concepts and constructs

3.1. Policy Variable (PV)

Policy Variable (PV) is a structure to keep interim results/meta data during the execution of an ECA script. For example, a PV could be used as an output parameter of an RPC invoked by ECA1 to be used in a condition expression for ECA2.

With respect to ECAs the scope of a PV is either global or (ECA) local. Global PVs are permanent. They are kept in the top level PV container and are shared between all ECAs of the script. Local PVs are kept within the internal PV container of an ECA. Local PVs could be either dynamic – appear/disappear with start/stop of the ECA execution, or static – exist as long as the ECA is configured.

Each PV has the following attributes:

- Globally or ECA scope unique name;
• type - either pre-defined (e.g. Boolean, integer, uint64, etc.) or specified via XPath pointing to a data store node or a sub-tree of the required structure. For example, PV named "Link" could be associated with the "/TE_Topologies/TE_Links/TE_Link" XPath in accordance with the TE Topology model [I-D.ietf-teas-yang-te-topo] and hence be capable of accommodating the entire TE Link container;

• value - data stored in the PV structured according to the PV type.

The following operations are allowed with/on a PV:

• initialize (with a constant/enum/identity);

• assign (with contents of another same type PV);

• read (retrieve data store contents pointed by the specified same type XPath/sub-tree);

• write (modify same type CONFIG=TRUE data store state with the PV’s content/value);

• insert (PV’s content into a same type list);

• iterate (copy into PV one by one same type list elements) (See examples of definition of and operations with PVs in Section 5).

• function calls in a form of F(dst, src), where F is an identity of a function from extendable function library, dst and src are destination and source PVs respectively, the function’s input parameters, with the result returned in dst.

Arbitrary expressions with PVs are for future study.

PVs could be used as input/output of an ECA invoked RPC. PVs could also be a source of information sent to the client in notification messages.

PVs could be used in condition expressions (see Section 5).

The model structure for the Policy Variable is shown below:
3.2. ECA Event

ECA Event is any subscribable event notification either explicitly defined in a YANG module supported by the server or a smart filter conveyed to the server via smart filter subscription. Additionally, an event could be associated with a one-time or periodic timer.

Event notification contents become in the ECA context implicit local dynamic PVs with automatically generated names. Let’s assume Network_Failure_Is_Detected event is defined that carries to a subscriber the detected failure type (failureType), ID (failureID) and the affected by the failure TE link state (teLInk). In the context of the associated with the Network_Failure_Is_Detected event ECA failureType, failureID and teLink are implicit local dynamic PVs that could be used in the embodied Condition and Action containers along with explicitly defined global and ECA local (static and/or dynamic) PVs.

One way to think of NETWONF/YANG Event Notification is as Remote Procedure Call-back, i.e. server->client directed RPC. When a subscribable NETWONF/YANG Event and associated with it ECA is pushed to the server within an ECA script, the server is expected to interpret this as follows: take the contents of the event notification and execute the logic defined by the associated Condition-Action chain (as I (client) would do on receipt of the notification) in order to decide how to react to the event. Recall that the whole purpose of ECA scripts is to reduce as much as possible the client-server communication.

A client may define an event of interest by making use of YANG PUSH smart filter/subscription. Specifically, the client may configure an ECA event according to the GNCA model specifying the event’s name, as well as the name of corresponding PUSH subscription. In this case the server is expected to:

- Register the event recording its name and using the referred PUSH subscription trigger as definition of the event firing trigger;
Auto-configure the event’s ECA input in the form of local PVs using the PUSH subscription’s filters;

At the moment of event firing intercept the notifications that would be normally sent to the PUSH subscription’s client(s); copy the data store states pointed by the PUSH subscription’s filters into the auto-configured ECA’s local PVs and execute the ECA’s condition-action chain.

All events (specified in at least one ECA pushed to the server) are required to be constantly monitored by the server. One way to think of this is that the server subscribes to its own publications with respect to all events that are associated with at least one ECA.

3.3. ECA Condition

ECA Condition is evaluated to TRUE or FALSE logical expression. There are two ways how an ECA Condition could be specified:

- in a form of XPath expression;
- as a hierarchy of comparisons and logical combinations of thereof.

The former option allows for specifying a condition of arbitrary complexity as a single string with an XPath expression, in which pertinent PVs and data store states are referred to by their respective positions in the YANG tree.

The latter option allows for configuring logical hierarchies. The bottom of said hierarchies are primitive comparisons (micro-conditions) specified in a form of:

\[ <\text{arg1}>\text{relation}\text{<arg2>} \]

where \text{arg1} and \text{arg2} represent either constant/enum/identity, PV or pointed by XPath data store node or sub-tree,

relation is one of the comparison operations from the set: \text{==, !=, >, <, >=, <=}

Primitive comparisons could be combined hierarchically into macro-conditions via && and || logical operations.

Regardless of the choice of their specification, ECA Conditions are associated with ECA Events and evaluated only within event threads triggered by the event detection.
When an ECA Condition is evaluated to TRUE, the associated with it ECA Action is executed.

The model structure for the ECA Condition is shown below:

```
+--rw conditions
  +--rw condition* [name]  
    +--rw name                      string
    +--rw (expression-choice)?  
      +--:(logical-operation)
        +--rw logical-operation-type?   identityref
        +--rw comparison-operation* [name]
          +--rw name                string
          +--rw comparision-type?   identityref
          +--rw arg1
            +--rw policy-argument
              +--rw type?                    identityref
              +--rw (argument-choice)?
                +--:(policy-constant)
                | +--rw constant?                string
                +--:(policy-variable)
                | +--rw policy-variable?         leafref
                +--:(local-policy-variable)
                | +--rw local-policy-variable?   leafref
                +--:(xpath)
                | +--rw xpath?                   string
            +--rw arg2
            +--rw policy-argument
              +--rw type?                    identityref
              +--rw (argument-choice)?
                +--:(policy-constant)
                | +--rw constant?                string
                +--:(policy-variable)
                | +--rw policy-variable?         leafref
                +--:(local-policy-variable)
                | +--rw local-policy-variable?   leafref
                +--:(xpath)
                | +--rw xpath?                   string
          +--rw sub-condition* [name]
            +--rw name    -> /gnca/conditions/condition/name
            +--:(xpath)
        | +--rw condition-xpath? string
```

The policy arguments arg1 and arg2 have the following structure:
3.4. ECA Action

ECA Action is one of the following operations to be carried out by a server:

- (-re)configuration - modifying a CONFIG=TRUE data store state
- (re-)configuration scheduling - scheduling one time or periodic (re-)configuration in the future
- sending one time notification;
- adding/removing event notify subscription (essentially, the same action as performed when a client explicitly adds/removes a subscription)
- executing an RPC defined by a YANG module supported by the server (the same action as performed when a client interactively calls the RPC);
- performing operations and function calls on PVs (such as assign, read, insert, iterate, etc);
- starting/stopping timers;
- stopping current ECA;
- invoking another ECA;
- NO-ACTION action – meaningful only within ECA’s Cleanup Condition-Action list to indicate that the ECA’s Normal Condition-Action thread must be terminated as soon as one of the required Actions is rejected by the server (see more Section 3.4).

Two points are worth noting:
1. When a NETWONF/YANG RPC appears in an ECA Action body, the server is expected to interpret this as follows: execute the same logic, as when the client explicitly calls said RPC via NETCONF. For example, when TE_Tunnel_Path_Computation RPC is found in the currently executed Action, the server is expected to call its TE path computation engine and pass to it the specified parameters in the Action input.

2. When a "Send notification" action is configured as an ECA Action, the notification message to be sent to the client may contain not only elements of the data store (as, for example, YANG PUSH or smart filter notifications do), but also the contents of global and local PVs, which store results of arbitrary operations performed on the data store contents (possibly over arbitrary period of time) to determine, for example, history/evolution of data store changes, median values, ranges and rates of the changes, results of configured function calls and expressions, etc. - in short, any data the client may find interesting about the associated event with all the logic to compute said data delegated to the server. Importantly, ECA notifications are the only ECA actions that directly interact with and hence need to be unambiguously understood by the client. Furthermore, the same ECA may originate numerous single or repetitive semantically different notifications within the same or separate event firings. In order to facilitate for the client the correlation of events and ECA notifications received from the server, the GNCA model requires each notification to carry mandatory information, such as event and (event scope unique) notification names.

Multiple ECA Condition/Action pairs could be combined into a macro-action.

Multiple ECA (macro-)Actions could be triggered by a single ECA event.

Any given ECA Condition or Action may appear in more than one ECAs.

The model structure for the ECA Action is shown below:
3.5. ECA

An ECA container includes:

- Event name
o List of local PVs. As mentioned, local PVs could be configured as
dynamic (their instances appear/disappear with start/stop of the
ECA execution) or static (their instances exist as long as the ECA
is configured). The ECA input (the contents of the associated
notification message, such as YANG PUSH or smart filter
notification message) are the ECA’s implicit local dynamic PVs with
automatically generated names

o Normal CONDITION-ACTION list: configured conditions each with
associated actions to be executed if the condition is evaluated to
TRUE

o Cleanup CONDITION-ACTION list: configured conditions/actions to be
evaluated/executed in case any Action from the Normal CONDITION-
ACTION list was attempted and rejected by the server. In other
words, this list specifies the ECA cleanup/unroll logic after
rejection of an Action from the Normal CONDITION-ACTION list. An
empty Cleanup CONDITION-ACTION list signifies that the ECA’s
normal Actions should be executed regardless of whether the
previously attempted ECA Actions were rejected or not by the
server. Cleanup CONDITION-ACTION list containing a single NO-
ACTION Action signifies that the ECA thread is to be immediately
terminated on rejection of any attempted Action (without executing
any cleanup logic)

4. Where ECA scripts are executed?

It could be said that the main idea of the GNCA is decoupling the
place where the network control logic is defined from the place where
it is executed. In previous sections of this document it is assumed
that the network control logic is defined by a client and pushed to
and executed by the network (server). This is accomplished via ECA
scripts, which are essentially bunches of regular NETCONF style
operations (such as get, set, call rpc) and event notifications glued
together via Policy Variables, PVs. It is worth noting that said ECA
scripts could be easily moved around and executed by any entity
supporting the GNCA YANG model (i.e. capable of interpreting the ECA
scripts). One interesting implication of this is that the ECA
scripts could be executed by neither client nor server, but a 3d
party entity, for instance, with a special focus on the control of a
particular network domain or/and special availability of/proximity to
information/resources that could contribute to the network control
decision process. For example, the ECA scripts could be pushed to a
Path Computation Element (PCE) adopted to support the GNCA YANG
model. Specialized ECA scripts could be fanned out to multiple
specialized controllers to take care of different aspects of a
network domain control.

Another interesting idea is to combine the GNCA with hierarchical T-SDN architecture. In particular, the ECA scripts conveyed by a client to a network orchestrator could be pushed (modified or unmodified) hierarchically down to lower level controllers. After all, the goal of the hierarchical T-SDN is to create a paradigm in which the higher level of a controller in the hierarchy, the broader (topologically and/or functionally) its control on the network and the lesser its involvement in the network’s micro-management in real time. On the other hand, it is desirable for a higher level controller to have a say as to how the subordinate controllers and, by extension, the network under control should deal with events and situations that are handled autonomously (i.e. without bothering the higher level controller in real time). The ECA scripts pushed down the T-SDN hierarchy may help to achieve this objective.

5. ECA script example

Consider a situation on a TE network when a network failure simultaneously affecting multiple TE tunnels. Normally, the TE network relies in this case on TE tunnels pre-configured protection/restoration capabilities and lets the TE tunnels to auto-recover themselves independently from each other. However, this default behavior may not be desired in some configurations/use cases because:

a. Recovery procedures of a "greedy" TE tunnel may block the recovery of other TE tunnels;

b. Shared mesh protection/restoration schemes are in place

In such cases the network has to perform the recovery of failure affected TE tunnels as a coordinated process. Furthermore, it is quite common that network resources available for the dynamic recovery procedures are limited, in which case it is desirable to convey to the network the policy/order in which the TE tunnels should be recovered. Different policies may be considered, to name a few:

1. Recover as many TE tunnels as possible;

2. Recover TE tunnels in accordance with their importance/priority;

3. Recover all unprotected TE tunnels before recovering broken connections/LSPs of protected TE tunnels (because the latter can tolerate the failure hopefully until it is repaired).

Let’s describe an ECA script that could be pushed by the controller application instructing the network to perform multiple TE tunnel failure recovery according to policy (3) above.
Assumptions: it is assumed that in one or several YANG modules supported by the server the following is defined:

- Subscribable "Network_Failure_Is_Detected" event carrying in the notification message the detected failure type (failureType), ID (failureID) and the affected by the failure TE link ID (linkID);

- RPC "PathDependsOnLink" taking as an input a TE_Path and TE_Link_ID and returning in its output Boolean indicating whether or not the specified path goes through the link with the specified ID;

- RPC "ReplaceTunnelsAwayFromLink" taking as an input a list of TE tunnel key leafrefs and ID of to be avoided link, performing the tunnel replacement away from the link and returning no output.

Explicit (global) PVs:

- name: Yes type: Boolean
- name: lsp xpath: /TE_Tunnels/lsp
- name tunnel xpath: /TE_Tunnels/te_tunnel
- name unprotected_tunnels xpath: /TE_Tunnels/te_tunnel/dependent_tunnels
- name protected_tunnels xpath: /TE_Tunnels/te_tunnel/dependent_tunnels

Actions:

name: PopulateTunnelLists

body:
lsp iterate xpath:/TE_Tunnels/lsp
{
    rpc: PathDependsOnLink(<lsp>/rro, Yes);
    if(Yes == TRUE )
    {
        tunnel = <lsp>/parent_tunnel;
        if(<tunnel>/protectionType == UNPROTECTED)
            <tunnel>/tunnelName insert unprotected_tunnels
        if(<tunnel>/protectionType != UNPROTECTED)
            <tunnel>/tunnelName insert protected_tunnels
    }
}

name: RepairTunnels

Body:

rpc: ReplaceTunnelsAwayFromLink(unprotected_tunnels, linkID);
rpc: ReplaceTunnelsAwayFromLink(protected_tunnels, linkID);

ECA:

eventName: Network_Failure_Is_Detected;

eventParams: failureType, failureID, linkID

Condition: TRUE (always, every time)

Actions:

unprotected_tunnels = 0; protected_tunnels =0;

namedAction: PopulateTunnelLists;

namedAction: RepairTunnels

Note: RPC "PathDependsOnLink" is used in the example for simplicity. The RPC could be easily replaced by a scripted named action similar to PopulateTunnelLists.

6. Complete Model Tree Structure

The complete tree structure of the YANG model defined in this document is as follows:
module: ietf-gnca
  +--rw gnca
