PCEP Extensions for service segment used in Segment Routing
draft-dw-pce-service-segment-routing-01

Abstract

Segment Routing (SR) technology leverages the source routing and
tunneling paradigms where a source node can choose a path without
relying on hop-by-hop signaling.

This document specifies extensions to the Path Computation Element
Protocol (PCEP) that allow a stateful PCE to compute and instantiate
SR-TE paths that also have a local service segments involved.

Status of This Memo

This Internet-Draft is submitted in full conformance with the
provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering
Task Force (IETF). Note that other groups may also distribute
working documents as Internet-Drafts. The list of current Internet-
Drafts is at http://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months
and may be updated, replaced, or obsoleted by other documents at any
time. It is inappropriate to use Internet-Drafts as reference
material or to cite them other than as "work in progress."

This Internet-Draft will expire on September 7, 2015.

1. Introduction

Segment Routing (SR) enables Traffic Engineering (TE) without relying
on a hop-by-hop signaling. It depends only on "segments" that are
advertised by Interior Gateway Protocols (IGPs). These segments made
by -

   o Node Segment
   o Adjacency Segment
   o Anycast Segment
   o IGP-Prefix Segment

Further to this list, a segment may also be identify a particular
value added service or service function (SF).
[I-D.filsfils-spring-segment-routing-use-cases] describes using local
Service-Segment to stand for a BGP-VPN service in an example. A
service-segment may also be used to represent specific treatment
offered by SR enabled node(s) in the path, a combination of node-
segment and service-segment can be used. The service segment is
local to the SR enabled node.
A stateful PCE can be used for computing one or more SR-TE paths taking into account various constraints and objective functions. Once a path is chosen, the stateful PCE can instantiate an SR-TE path on a PCC using PCEP extensions specified in [I-D.ietf-pce-segment-routing].

An SR-TE path is defined as a path that consists of one or more SID(s) where each SID is associated with the identifier that represents the node or adjacency corresponding to the SID. This document extends the SR-TE path to use Service-SID(s) in the path as well.

The means by which the PCE learns about the Service-SID (e.g., learnt over a management interface or through a variety of other mechanisms) is beyond scope of this document.

2. Conventions used in this document

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC2119 [RFC2119].

2.1. Terminology

The following terminologies are used in this document:

- ERO: Explicit Route Object
- IGP: Interior Gateway Protocol
- LSR: Label Switching Router
- PCC: Path Computation Client
- PCE: Path Computation Element
- PCEP: Path Computation Element Protocol
- SF: Service Function
- SFC: Service Function Chaining
- SID: Segment Identifier
- SR: Segment Routing
- SR-ERO: Segment Routed Explicit Route Object
3. Overview of PCEP Operation in SR Networks for Service Chaining

In SR networks, an ingress node of an SR path appends all outgoing packets with an SR header consisting of a list of Segment IDs (SIDs). The header has all necessary information to guide the packets from the ingress node to the egress node of the path, and hence there is no need for any signaling protocol. In the [I-D.ietf-pce-segment-routing], an SID represents either a nodal segment representing a path to a node or adjacency segment representing path over a specific adjacency. In this document, we allow SID also can represent a service segment representing a specific treatment or SF.

In a PCEP session, path information is carried in the Explicit Route Object (ERO), which consists of a sequence of subobjects. In this document, a PCE needs to specify EROs containing SID of service segments (or service-SID), and a PCC needs to be capable of processing such ERO sub-objects.

The SR-ERO Subobject defined in the [I-D.ietf-pce-segment-routing] can be used to carry SID of service segment. An SR-ERO containing SID of service segment can be included in the same PCEP messages specified in the [I-D.ietf-pce-segment-routing].

When a PCEP session between a PCC and a PCE is established, the corresponding PCEP operation is same as defined in the [I-D.ietf-pce-segment-routing].

4. Object Formats

In the [I-D.ietf-pce-segment-routing], an SR-TE path is defined as a path that consists of one or more SID(s) where each SID is associated with the identifier that represents the node or adjacency corresponding to the SID. In this document, we allow the SR-TE path to include one or more SID of service segments (called service-SID) that are inserted along with node segments in SR-TE path. A service-segment may also be used to represent a set of SF instances. The service-SID is local to the node where the service resides, thus a combination of node-segment and service-segment are used together.
The SR-ERO Subobject extension for service segment support

The SR-ERO Subobject is defined in section 5.3.1 of [I-D.ietf-pce-segment-routing] and as a mandatory subobject used to advertise SID and NAI ('Node or Adjacency Identifier') associated with SID. In this document, we extend the existing SR-ERO Subobject as specified in section 5.3.1 of [I-D.ietf-pce-segment-routing] to represent service-SID of the service segment.

The SR-ERO Subobject as described in [I-D.ietf-pce-segment-routing]:

```
          0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1
        +--------------------------------------------------+
        | L |    Type     |     Length    |  ST   |     Flags     |F|S|C|M|  
        +--------------------------------------------------+
        |                              SID                              |
        +--------------------------------------------------+
        |                        NAI (variable)                        |
        +--------------------------------------------------+
```

L

The L bit SHOULD NOT be set, so that the subobject represents a strict hop in the explicit route in case of service-segment.

Type

The Type is as per [I-D.ietf-pce-segment-routing].

Length

The Length is as per [I-D.ietf-pce-segment-routing].

ST

The ST (SID Type) field is set to specify service-SID. A new SID-Type values is to be assigned.

Flags

All flags (M, C, S, F bit) are as per [I-D.ietf-pce-segment-routing].
SID

The SID value represents an service segment as described in [I-D.filsfils-spring-segment-routing-use-cases].

NAI

The NAI for service-segment may be defined in future based on the service.

4.2. Service Segment SR-ERO Processing

When the SID represents a service segment (as per the SID Type - ST field), its value is local to node segment offering the service. Thus Service-SID MUST be associated with a node-SID preceding it in the SR-ERO. Note that multiple services may be offered by the same node, and in this case node-SID maybe followed by multiple Service-SID. NAI value for service-SID may be defined in future.

If a service segment (or service-SID) cannot be associated with a node segment (or node-SID), PCEP speaker MUST send a PCE error with Error-Type = "Reception of an invalid object" and Error-Value = "Segment List Order Error".

The rest of the processing rules are as per [I-D.ietf-pce-segment-routing].

5. Backward Compatibility

Backward Compatibility consideration described in section 8 of [I-D.ietf-pce-segment-routing] can be applied for service segment support as well.

6. Management Considerations

Management consideration described in section 9 of [I-D.ietf-pce-segment-routing] can be applied to service segment support as well.

7. Security Considerations

The security considerations described in [RFC5440] and [I-D.ietf-pce-segment-routing] apply.
8. IANA Considerations

TBD.

Appendix A. Examples

Consider the below example-

```
+---------+        +---------+        +---------+        +---------+
|         |        |         |        |         |
|         |        |         |        |         |
|         |        |         |        |         |
|         |        |         |        |         |
|         |        |         |        |         |
|         |        |         |        |         |
|         |        |         |        |         |
+---------+        +---------+        +---------+        +---------+
|      |        |      |        |      |        |      |
|      |        |      |        |      |        |      |
|      |        |      |        |      |        |      |
|      |        |      |        |      |        |      |
|      |        |      |        |      |        |      |
|      |        |      |        |      |        |      |
|      |        |      |        |      |        |      |
N1      N2          N3          N4
```
o N1 is Ingress;
o N4 is Egress;
o N2 has two services hosted identified as S1 and S2;
o N3 has one service hosted identified as S3.

The SR-ERO for the SR-TE path including the service segment would be

\[
\{(\text{SID}_N2, \text{SID}_S1, \text{SID}_S2), (\text{SID}_N3, \text{SID}_S3), (\text{SID}_N4)\}
\]
