Overview

This document describes the MIME header Content-Duration that is intended for use with any timed media content (typically audio/* or video/*).

1. Abstract

This document describes the MIME header Content-Duration that is intended for use with any timed media content (typically audio/* or video/*). The length of time is represented in seconds.

2. Content-Duration Header Field

Many media contents have an inherent time duration, for example a spoken message or a video clip. Many audio and video encodings may include their length as header information or may allow accurate calculation based on the byte length of the data. However, it may be useful to present the time duration of the content in a MIME header to allow its simple determination without dealing with the actual content.

2.1 Syntax

The Content-Duration field’s value is a single number specifying the
time duration in seconds of the content. Formally:

duration := "Content-Duration" :: 1*10DIGIT

Note that practically (though highly unlikely in MIME media), the upper bound on the numerical value of the superior time unit is 
$(2^{^31} - 1)$ or 2147483647.

2.2 Semantics

This field represents the time duration of the associated content. The time duration is noted in seconds with no units tag. The time value should be exact, however the exact value of the time duration cannot be known without opening the content and playing it. If an exact value must be known, then the latter method should be used. This mechanism simply allows placing a sender determined time duration value in the header for easy access.

Though there are several ways to present this duration to the recipient (e.g. with the inbox headers, when audio attachment opened), the actual use of this field on reception is a local implementation issue.

2.3 Example

In this example the content duration represents 33 seconds:

    Content-Duration: 33
3. VPIM Usage

The Content-Duration header field for audio/32KADPCM sub-type is a useful component of the VPIM specification [VPIM2]. All VPIM Messages MUST contain this sub-type to carry the audio of a voice message. It may be useful in some instances (e.g. viewing on a simple MIME or non-MIME desktop) to have the time duration of the voice message available without having to open the audio content.

4. Security considerations:

This definition introduces the option of explicitly identifying the time duration of an audio/* or fax/* content outside of the binary data that forms the content. In some environments (though likely not the majority), the identification of the actual time duration in a header field may be a security issue and as a result should not be noted.
