This document describes how to use IP-based emergency services mechanisms to support the next generation of emergency calls placed by vehicles (automatically in the event of a crash or serious incident, or manually invoked by a vehicle occupant) and conveying vehicle, sensor, and location data related to the crash or incident. Such calls are often referred to as "Automatic Crash Notification" (ACN), or "Advanced Automatic Crash Notification" (AACN), even in the case of manual trigger. The "Advanced" qualifier refers to the ability to carry a richer set of data.

This document also registers a MIME Content Type and an Emergency Call Additional Data Block for the vehicle, sensor, and location data (often referred to as "crash data" even though there is not necessarily a crash).

Profiling and simplifications are possible due to the nature of the functionality that is provided in vehicles with the usage of Global Satellite Navigation System (GNSS).

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at http://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."
1. Terminology

1. Terminology
The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119].

This document re-uses terminology defined in Section 3 of [RFC5012].

Additionally, we use the following abbreviations:

3GPP: 3rd Generation Partnership Project
AACN: Advanced Automatic Crash Notification
ACN: Automatic Crash Notification
APCO: Association of Public-Safety Communications Officials
EENA: European Emergency Number Association
ESInet: Emergency Services IP network
GNSS: Global Satellite Navigation System (which includes the various such systems including the Global Positioning System or GPS)
IVS: In-Vehicle System
MNO: Mobile Network Operator
NENA: National Emergency Number Association
TSP: Telematics Service Provider
VEDS: Vehicle Emergency Data Set

2. Introduction

Emergency calls made by in-vehicle systems (e.g., in the event of a crash) assist in significantly reducing road deaths and injuries by allowing emergency services to respond quickly and often with better location.

Drivers often have a poor location awareness, especially outside of major cities, at night and when away from home (especially abroad). In the most crucial cases, the victim(s) may not be able to call because they have been injured or trapped.

For more than a decade, some vehicles have been equipped with telematics systems that, among other features, place an emergency call automatically in the event of a crash or manually in response to
an emergency call button. Such systems generally have on-board location determination systems that make use of satellite-based positioning technology, inertial sensors, gyroscopes, etc., to provide a fairly accurate position for the vehicle. Such built-in systems can take advantage of the benefits of being integrated into a vehicle, such as more reliable power, ability to have larger or specialized antenna, ability to be engineered to avoid or minimise degradation by vehicle glass coatings, interference from other vehicle systems, etc. Thus, the PSAP can be provided with a good estimate of where the vehicle is during an emergency. Vehicle manufacturers are increasingly adopting such systems, both for the safety benefits and for the additional features and services they enable (e.g., remote engine diagnostics, remote door unlock, stolen vehicle tracking and disabling, etc.).

The general term for such systems is Automatic Crash Notification (ACN) or "Advanced Automatic Crash Notification" (AACN). "ACN" is used in this document as a general term. ACN systems transmit some amount of data specific to the incident, referred to generally as "crash data." While different systems transmit different amounts of crash data, standardized formats, structures, and mechanisms are needed to provide interoperability among systems and PSAPs.

Currently deployed in-vehicle telematics systems are circuit-switched and lack a standards-based ability to convey crash data directly to the PSAP (generally relying on either a human call taker or an automated system to provide the PSAP call taker with some crash data orally, or possibly a proprietary mechanism) and are difficult to extend as new sensors are added.

The transition to next-generation calling in general, and emergency calling in particular, provides an opportunity to vastly improve the scope, breadth, reliability and usefulness of crash data during an emergency by allowing it to be presented alongside the call, and to be automatically processed by the PSAP and made available to the call taker in an integrated, automated way. In addition, vehicle manufacturers are provided an opportunity to take advantage of the same standardized mechanisms for data transmission for internal use if they wish (such as telemetry between the vehicle and a service center for both emergency and non-emergency uses, including location-based services, multi-media entertainment systems, and road-side assistance applications).

Next-generation ACN provides an opportunity for such calls to be recognized and processed as such during call set-up, and routed to a specialized PSAP where the vehicle data is available to assist the call taker in assessing and responding to the situation.
An ACN call may be either occupant-initiated or automatically triggered. (The "A" in "ACN" does stand for "Automatic," but the term is often used to refer to the class of calls that are placed by an in-vehicle system (IVS) and that carry incident-related data as well as voice.) Automatically triggered calls indicate a car crash or some other serious incident (e.g., a fire) and carry a greater presumption of risk of injury. Manually triggered calls are often reports of serious hazards (such as drunk drivers) and may require different responses depending on the situation. Manually triggered calls are also more likely to be false (e.g., accidental) calls and may thus be subject to different handling by the PSAP.

This document describes how the IETF mechanisms for IP-based emergency calls, including [RFC6443] and [additional-data-draft], are used to provide the realization of next-generation ACN.

The Association of Public-Safety Communications Officials (APCO) and the National Emergency Number Association (NENA) have jointly developed a standardized set of incident-related vehicle data for ACN use, called the Vehicle Emergency Data Set (VEDS) [VEDS]. Such data is often referred to as crash data although it is applicable in incidents other than crashes.

VEDS provides a standard data set for the transmission, exchange, and interpretation of vehicle-related data. A standard data format allows the data to be generated by an IVS, and interpreted by PSAPs, emergency responders, and medical facilities (including those capable of providing trauma level patient care). It includes incident-related information such as airbag deployment, location of the vehicle, if the vehicle was involved in a rollover, various sensor data that can indicate the potential severity of the crash and the likelihood of severe injuries to the vehicle occupants, etc. This data better informs the PSAP and emergency responders as to the type of response that may be needed. This information was recently included in the federal guidelines for field triage of injured patients. These guidelines are designed to help responders at the accident scene identify the potential existence of severe internal injuries and to make critical decisions about how and where a patient needs to be transported.

This document registers the ‘application/EmergencyCallData.VEDS+xml’ MIME content-type, and registers the ‘VEDS’ entry in the Emergency Call Additional Data registry.
VEDS is an XML structure (see [VEDS]). The ‘application/EmergencyCallData.VEDS+xml’ MIME content-type is used to identify it. The ‘VEDS’ entry in the Emergency Call Additional Data registry is used to construct a ‘purpose’ parameter value for conveying VEDS data in a Call-Info header (as described in [additional-data-draft]).

VEDS is a versatile structure that can accommodate varied needs. However, if additional sets of data are determined to be needed, the steps to enable each data block are very briefly summarized below:

- A standardized format and encoding (such as XML) is defined and published by a Standards Development Organization (SDO).
- A MIME Content-Type is registered for it (typically under the ‘Application’ media type and with a sub-type starting with ‘EmergencyCallData.’).
- An entry for the block is added to the Emergency Call Additional Data Blocks sub-registry (established by [additional-data-draft]); the registry entry is the root of the MIME sub-type (not including the ‘EmergencyCallData’ prefix and any suffix such as ‘+xml’).

A next-generation In-Vehicle System (IVS) transmits crash data by encoding it in a standardized and registered format (such as VEDS) and attaching it to an INVITE as a MIME body part. The body part is identified by its MIME content-type (such as ‘application/EmergencyCallData.VEDS+xml’) in the Content-Type header field of the body part. The body part is assigned a unique identifier which is listed in a Content-ID header field in the body part. The INVITE is marked as containing the crash data by adding (or appending to) a Call-Info header field at the top level of the INVITE. The Call-Info header field contains a CID URL referencing the body part’s unique identifier, and a ‘purpose’ parameter identifying the data as the crash data per the registry entry; the ‘purpose’ parameter’s value is ‘EmergencyCallData.’ and the root of the MIME type (not including the ‘EmergencyCallData’ prefix and any suffix such as ‘+xml’ (e.g., ‘purpose=EmergencyCallData.VEDS’)).

The mechanisms described here can be used place emergency calls that are identifiable as ACN calls and that carry one or more standardized crash data objects in an interoperable way.

Note that while ACN systems in the U.S. and other regions are not currently mandated, Europe has a mandated and standardized system for emergency calls by in-vehicle systems. This pan-European system is known as "eCall" and is not further discussed in this document but is the subject of a separate document, [eCall-draft]

3. Overview of Current Deployment Models
Current (circuit-switched or legacy) systems for placing emergency calls by in-vehicle systems, including automatic crash notification systems, generally have a limited ability to convey at least location and in some cases telematics data to the PSAP. Most such systems use one of three architectural models, which are described here as: "Telematics Service Provider" (TSP), "direct", and "paired handset". These three models are illustrated below.

In the TSP model, both emergency and non-emergency calls are placed to a Telematics Service Provider (TSP); a proprietary technique is used for data transfer (such as proprietary in-band modems) to the TSP.

In an emergency, the TSP call taker bridges in the PSAP and communicates location, crash data (such as impact severity and trauma prediction), and other data (such as the vehicle description) to the PSAP call taker verbally. Typically, a three-way voice call is established between the vehicle, the TSP, and the PSAP, allowing communication between the PSAP call taker, the TSP call taker, and the vehicle occupants (who might be unconscious).

```
/---/ proprietary +-----+ 911 trunk +-----+
\ | | IVS | |----------------+ TSP +------------------+ PSAP |
 \ | | crash data +-----+ +-----+
```

Figure 1: Legacy TSP Model.

In the paired model, the IVS uses a Bluetooth link with a previously-paired handset to establish an emergency call with the PSAP (by dialing a standard emergency number such as 9-1-1), and then communicates location data to the PSAP via text-to-speech; crash data is not conveyed. Some such systems use an automated voice prompt menu (e.g., "this is an automatic emergency call from a vehicle; press 1 to open a voice path to the vehicle; press 2 to hear the location read out") to allow the call taker to request location data via text-to-speech.

```
+-----+ 911/etc voice call via handset +-----+
/---/ | H | IVS | |---|+-----| S +------------------->+ PSAP |
\ | | ++----- location via text-to-speech ++-----+
```

Figure 2: Legacy Paired Model.

In the direct model, the IVS directly places an emergency call with the PSAP by dialing a standard emergency number such as 9-1-1. Such
systems might communicate location data to the PSAP via text-to-speech; crash data might not be conveyed.

```
911/etc voice call via IVS +------+
IVS -------------------------------+ PSAP |
location via text-to-speech +------+
```

Figure 3: Legacy Direct Model

4. Document Scope

This document is focused on the interface to the PSAP, that is, how an ACN emergency call is setup and incident-related data (including vehicle, sensor, and location data) is transmitted to the PSAP using IETF specifications. (The goal is to re-use specifications rather than to invent new.) For the direct model, this is the end-to-end description (between the vehicle and the PSAP). For the TSP model, this describes the right-hand side (between the TSP and the PSAP), leaving the left-hand side (between the vehicle and the TSP) up to the entities involved (i.e., IVS and TSP vendors) who are then free to use the same mechanism as for the right-hand side (or not).

This document does not address pan-European eCall (a mandated and standardized system for emergency calls by in-vehicle systems within Europe and other regions), which is the subject of a separate document, [eCall-draft]

5. Migration to Next-Generation

Migration of emergency calls placed by in-vehicle systems to next-generation (all-IP) technology provides a standardized mechanism to identify such calls and to present crash data with the call. This allows ACN calls and crash data to be automatically processed by the PSAP and made available to the call taker in an integrated, automated way.

Vehicle manufacturers using the TSP model may choose to take advantage of the same mechanism to carry telematics data between the vehicle and the TSP for both emergency and non-emergency calls.

A next-generation IVS establishes an emergency call using the 3GPP IMS solution with a Request-URI indicating an ACN type of emergency call with vehicle data attached; the MNO only needs to recognize the call as an emergency call and route it to an ESInet; the ESInet recognizes the call as an ACN with vehicle data and routes the call to an NG-ACN capable PSAP; the PSAP interprets the vehicle data sent with the call and makes it available to the call taker.
Because of the need to identify and specially process Next-Generation
ACN calls (as discussed above), this document registers new service
URN children within the "sos" subservice. These URNs provide the
mechanism by which an NG-ACN call is identified, and differentiate
between manually and automatically triggered NG-ACN calls (which may
be subject to different treatment, depending on policy). The two
service URNs are: ‘urn:service:sos.vehicle.automatic’ and
‘urn:service:sos.vehicle.manual’.

Migration of the three architectural models to next-generation (all-
IP) is described below.

In the TSP model, the IVS transmits crash and location data to the
TSP using either a protocol that is based on a proprietary design or
one that re-uses IETF specifications. In an emergency, the TSP call
taker bridges in the PSAP and the TSP transmits crash and other data
to the PSAP using IETF specifications. There is a three-way call
between the vehicle, the TSP, and the PSAP, allowing communication
between the PSAP call taker, the TSP call taker, and the vehicle
occupants (who might be unconscious).

 proprietary
 ///-----\\  or standard +-------+ standard +-------+
 ||| IVS ||| ------------------->+ TSP +---------------+--->+ PSAP |
 \\\-----///  crash + other data +-------+ crash + other data +-------+

Figure 4: Next-Generation TSP Model

The vehicle manufacturer and the TSP may choose to use the same IETF
specifications to transmit crash and location data from the vehicle
to the TSP as is described here to transmit such data from the TSP to
the PSAP.

In the paired model, the IVS uses a Bluetooth link to a previously-
paired handset to establish an emergency call with the PSAP; it is
not clear what facilities are or will be available for transmitting
crash data through the Bluetooth link.

Figure 5: Next-Generation Paired Model

In the direct model, the IVS communicates crash data to the PSAP
directly using IETF specifications.
6. Profile

In the context of emergency calls placed by an in-vehicle system it is assumed that the car is equipped with a built-in GNSS receiver. For this reason only geodetic location information will be sent within an emergency call. The following location shapes MUST be implemented: 2d and 3d Point (see Section 5.2.1 of [RFC5491]), Circle (see Section 5.2.3 of [RFC5491]), and Ellipsoid (see Section 5.2.7 of [RFC5491]). The coordinate reference systems (CRS) specified in [RFC5491] are also mandatory for this document. The <direction> element, as defined in [RFC5962] which indicates the direction of travel of the vehicle, is important for dispatch and hence it MUST be included in the PIDF-LO. The <heading> element specified in [RFC5962] MUST be implemented and MAY be included.

Calls by in-vehicle systems are placed via cellular networks, which may ignore location sent by an originating device in an emergency call INVITE, instead attaching their own location (often determined in cooperation with the originating device). The IVS MAY attach location data to the call INVITE. Standardized crash data structures often include location as determined by the IVS. A benefit of this is that it allows the PSAP to see both the location as determined by the cellular network (often in cooperation with the originating device) and the location as determined by the IVS.

This specification also inherits the ability to utilize test call functionality from Section 15 of [RFC6881].

7. Call Setup

It is important that ACN calls be easily identifiable as such at all stages of call handling, and that automatic versus manual triggering be known. ACN calls differ from general emergency calls in several aspects, including the presence of standardized crash data, the fact that the call is known to be placed by an in-vehicle system (which has implications for PSAP operational processes), and, especially for automatic calls, information that may indicate a likelihood of severe injury and hence need for trauma services. Knowledge that a call is an ACN and further that it was automatically or manually invoked carries a range of implications about the call, the circumstances, and the vehicle occupants. Calls by in-vehicle systems may be considered a specific sub-class of general emergency calls and need...
to be handled by a PSAP with the technical and operational capabilities to serve such calls. (This is especially so in environments such as the U.S. where there are many PSAPs and where individual PSAPs have a range of capabilities.) Technical capabilities include the ability to recognize and process standardized crash data. Operational capabilities include training and processes for assessing severe injury likelihood and responding appropriately (e.g., dispatching trauma-capable medical responders, transporting victims to a trauma center, alerting the receiving facility, etc.).

Because ACN calls differ in significant ways from general emergency calls, and because such calls need to be handled by specialized PSAPs (equipped technically to interpret and make use of crash data, and operationally to handle emergency calls placed by in-vehicle systems), this document proposes an SOS sub-service for ACN/car crash, specifically, "SOS.vehicle". Using a sub-service makes it readily obvious that the call is an ACN; a further child elements is proposed to distinguish calls automatically placed due to a crash or other serious incident (such as a fire) from those manually invoked by a vehicle occupant (specifically, "SOS.vehicle.automatic" and "SOS.vehicle.manual"). The distinction between automatic and manual invocation is also significant; automatically triggered calls indicate a car crash or some other serious incident (e.g., a fire) and carry a greater presumption of risk of injury and hence need for specific responders (such as trauma or fire). Manually triggered calls are often reports of serious hazards (such as drunk drivers) and may require different responses depending on the situation. Manually triggered calls are also more likely to be false (e.g., accidental) calls and may thus be subject to different handling by the PSAP.

A next-generation In-Vehicle System (IVS) transmits crash data by encoding it in a standardized and registered format and attaching it to an INVITE as an additional data block as specified in Section 4.1 of [additional-data-draft]. As described in that document, the block is identified by its MIME content-type, and pointed to by a CID URL in a Call-Info header with a ‘purpose’ parameter value corresponding to the block.

Specifically, the steps required during standardization are:

- A set of crash data is standardized by an SDO or appropriate organization
- A MIME Content-Type for the crash data set is registered with IANA
If the data is specifically for use in emergency calling, the MIME type is normally under the ‘application’ type with a subtype starting with ‘EmergencyCallData.’

If the data format is XML, then by convention the name has a suffix of ‘+xml’.

The item is registered in the Emergency Call Additional Data registry, as defined in Section 9.1.7 of [additional-data-draft].

For emergency-call-specific formats, the registered name is the root of the MIME Content-Type (not including the ‘EmergencyCallData’ prefix and any suffix such as ‘+xml’) as described in Section 4.1 of [additional-data-draft].

When placing an emergency call:

- The crash data set is created and encoded per its specification.
- The crash data set is attached to the emergency call INVITE as specified in Section 4.1 of [additional-data-draft], that is, as a MIME body part identified by its MIME Content-Type in the body part’s Content-Type header field.
- The body part is assigned a unique identifier label in a Content-ID header field of the body part.
- A Call-Info header field at the top level of the INVITE references the crash data and identifies it by its MIME root (as registered in the Emergency Call Additional Data registry).

- The crash data is referenced in the Call-Info header field by a CID URL that contains the unique Content ID assigned to the crash data body part.
- The crash data is identified in the Call-Info header field by a ‘purpose’ parameter whose value is ‘EmergencyCallData.’ concatenated with the specific crash data entry in the Emergency Call Additional Data registry.
- The Call-Info header field MAY be either solely to reference the crash data (and hence have only the one URL) or may also contain other URLs referencing other data.
- Additional crash data sets MAY be included by following the same steps.
The Vehicle Emergency Data Set (VEDS) is an XML structure defined by the Association of Public-Safety Communications Officials (APCO) and the National Emergency Number Association (NENA) [VEDS]. The 'application/EmergencyCallData.VEDES+xml' MIME content-type is used to identify it. The 'VEDES' entry in the Emergency Call Additional Data registry is used to construct a 'purpose' parameter value for conveying VEDS data in a Call-Info header.

The VEDS data is attached as a body part with MIME content type 'application/EmergencyCallData.VEDES+xml' which is pointed at by a Call-Info URL of type CID with a 'purpose' parameter of 'EmergencyCallData.VEDES'.

Entities along the path between the vehicle and the PSAP are able to identify the call as an ACN call and handle it appropriately. The PSAP is able to identify the crash data as well as any other additional data attached to the INVITE by examining the Call-Info header fields for 'purpose' parameters whose values start with 'EmergencyCallData.' The PSAP is able to access and the data it is capable of handling and is interested in by checking the 'purpose' parameter values.

8. Call Routing

An Emergency Services IP Network (ESInet) is a network operated by emergency services authorities. It handles emergency call routing and processing before delivery to a PSAP. In the NG9-1-1 architecture adopted by NENA as well as the NG1-1-2 architecture adopted by EENA, each PSAP is connected to one or more ESInets. Each originating network is also connected to one or more ESInets. The ESInets maintain policy-based routing rules which control the routing and processing of emergency calls. The centralization of such rules within ESInets provides for a cleaner separation between the responsibilities of the originating network and that of the emergency services network, and provides greater flexibility and control over processing of emergency calls by the emergency services authorities. This makes it easier to react quickly to unusual situations that require changes in how emergency calls are routed or handled (e.g., a natural disaster closes a PSAP), as well as ease in making long-term changes that affect such routing (e.g., cooperative agreements to specially handle calls requiring translation or relay services).
In an environment that uses ESInets, the originating network need only detect that the service URN of an emergency call is or starts with "sos", passing all types of emergency calls to an ESInet. The ESInet is then responsible for routing such calls to an appropriate PSAP. In an environment without an ESInet, the emergency services authorities and the originating carriers would need to determine how such calls are routed.

9. Test Calls

This specification also inherits the ability to utilize test call functionality from Section 15 of [RFC6881].

A service URN starting with "test." indicates a request for an automated test. For example, "urn:service:test.sos.vehicle.automatic" indicates such a test feature. This functionality is defined in [RFC6881].

10. Example

Figure 7 shows an emergency call placed by a vehicle whereby location information and VEDS crash data are both attached to the SIP INVITE message. The INVITE has a request URI containing the ‘urn:service:sos.vehicle.automatic’ service URN and is thus recognized as an ACN type of emergency call, and is also recognized as a type of emergency call because the request URI starts with ‘urn:service:sos’. The mobile network operator (MNO) routes the call to an Emergency services IP Network (ESInet), as for any emergency call. The ESInet processes the call as an ACN and routes the call to an appropriate ACN-capable PSAP (using location information and the fact that that it is an ACN). (In deployments where there is no ESInet, the MNO itself needs to route directly to an appropriate ACN-capable PSAP.) The call is processed by the Emergency Services Routing Proxy (ESRP), as the entry point to the ESInet. The ESRP routes the call to an appropriate ACN-capable PSAP, where the call is received by a call taker.

Figure 7: Example of Vehicle-Placed Emergency Call Message Flow
11. Security Considerations

This document does not raise security considerations beyond those described in [RFC5069]. As with emergency service systems with end host provided location information there is the possibility that that location is incorrect, either intentionally (in case of an a denial of service attack against the emergency services infrastructure) or due to a malfunctioning devices. The reader is referred to [I-D.ietf-ecrit-trustworthy-location] for a discussion of some of these vulnerabilities.

12. IANA Considerations

12.1. Service URN Registration

IANA is requested to register the URN ‘urn:service:sos.vehicle’ under the sub-services ‘sos’ registry defined in Section 4.2 of [RFC5031].

This service identifier reaches a public safety answering point (PSAP), which in turn dispatches aid appropriate to the emergency
related to accidents of vehicles. The following two sub-services are registered as well:

urn:service:sos.vehicle.manual

This service URN indicates that an emergency call carrying vehicle sensor ("crash") data has been placed by an in-vehicle system (IVS) based on the manual interaction of the driver or a passenger.

urn:service:sos.vehicle.automatic

This service URN indicates that an emergency call carrying vehicle sensor ("crash") data has been placed by an in-vehicle system (IVS) triggered automatically, for example, due to a crash.

12.2. MIME Content-type Registration for ‘application/EmergencyCall.VEDS+xml’

This specification requests the registration of a new MIME type according to the procedures of RFC 4288 [RFC4288] and guidelines in RFC 3023 [RFC3023].

MIME media type name: application

MIME subtype name: EmergencyCallData.VEDS+xml

Mandatory parameters: none

Optional parameters: charset

Indicates the character encoding of enclosed XML.

Encoding considerations: Uses XML, which can employ 8-bit characters, depending on the character encoding used. See Section 3.2 of RFC 3023 [RFC3023].

Security considerations: This content type is designed to carry vehicle crash data during an emergency call. This data may contains personal information including vehicle VIN, location, direction, etc. appropriate precautions need to be taken to limit unauthorized access, inappropriate disclosure to third parties, and eavesdropping of this information. Please refer to Section 7 and Section 8 of [additional-data-draft] for more information.

Interoperability considerations: None

Published specification: [VEDS]
12.3. Registration of the ‘VEDS’ entry in the Emergency Call Additional Data registry

This specification requests IANA to add the ‘VEDS’ entry to the Emergency Call Additional Data registry, with a reference to this document. The Emergency Call Additional Data registry has been established by [additional-data-draft].

13. Contributors

We would like to thank Ulrich Dietz for his help with earlier versions of the original version of this document.

14. Acknowledgements

We would like to thank Michael Montag, Arnoud van Wijk, Ban Al-Bakri, and Gunnar Hellstrom for their feedback.

15. Changes from Previous Versions

15.1. Changes from -01 to -02

  o Fixed case of ‘EmergencyCallData’, in accordance with changes to [additional-data-draft]

15.2. Changes from -00 to -01
Internet-Draft Next-Generation In-Vehicle Emergency Calls  February 2014

- Now using ‘EmergencyCallData’ for purpose parameter values and MIME subtypes, in accordance with changes to [additional-data-draft]
- Added reference to RFC 6443
- Fixed bug that caused Figure captions to not appear
