The Constrained RESTful Application Language (CoRAL)
draft-hartke-t2trg-coral-06

Abstract

The Constrained RESTful Application Language (CoRAL) defines a data model and interaction model as well as two specialized serialization formats for the description of typed connections between resources on the Web ("links"), possible operations on such resources ("forms"), as well as simple resource metadata.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at https://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on April 25, 2019.

1. Introduction

The Constrained RESTful Application Language (CoRAL) is a language for the description of typed connections between resources on the Web ("links"), possible operations on such resources ("forms"), as well as simple resource metadata.

CoRAL is intended for driving automated software agents that navigate a Web application based on a standardized vocabulary of link and form relation types. It is designed to be used in conjunction with a Web transfer protocol such as the Hypertext Transfer Protocol (HTTP) [RFC7230] or the Constrained Application Protocol (CoAP) [RFC7252].

This document defines the CoRAL data and interaction model, as well as two specialized CoRAL serialization formats:

The CoRAL data and interaction model is a superset of the Web Linking model of RFC 8288 [RFC8288]. The CoRAL data model consists of two elements: _links_ that describe the relationships between pairs of resources and the type of those relationships, and _forms_ that describe possible operations on resources and the type of those operations. Additionally, the data model can describe simple resource metadata in a way similar to the Resource Description Framework (RDF) [W3C.REC-rdf11-concepts-20140225]. In contrast to RDF, the focus of CoRAL is on the interaction with resources, not just the relationships between them. The CoRAL interaction model derives from HTML 5 [W3C.REC-html52-20171214] and specifies how an automated software agent can navigate between resources by following links and perform operations on resources by submitting forms.

The primary CoRAL serialization format is a compact, binary encoding of links and forms in Concise Binary Object Representation (CBOR) [RFC7049]. It is intended for environments with constraints on power, memory, and processing resources [RFC7228] and shares many similarities with the message format of the Constrained Application Protocol (CoAP) [RFC7252].
Protocol (CoAP) [RFC7252]. For example, it uses numeric identifiers instead of verbose strings for link and form relation types, and pre-parses URIs into (what CoAP considers to be) their components, which greatly simplifies URI processing. As a result, link serializations are often much more compact than equivalent serializations in CoRE Link Format [RFC6690] [I-D.ietf-core-links-json].

The secondary CoRAL serialization format is a lightweight, textual encoding of links and forms that is intended to be easy to read and write for humans. The format is loosely inspired by the syntax of Turtle [W3C.REC-turtle-20140225] and is used throughout the document for examples.

1.1. Requirements Notation

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [RFC2119] [RFC8174] when, and only when, they appear in all capitals, as shown here.

2. Examples

2.1. Web Linking

At its core, CoRAL is just yet another serialization format for Web links. For example, if an HTTP client sends the following request:

GET /TheBook/chapter3 HTTP/1.1
Host: example.com

and receives the following response:

HTTP/1.1 200 OK
Content-Type: text/coral

#using <http://www.iana.org/assignments/relation/>

next    <./chapter4>
icon    </favicon.png>
license <http://creativecommons.org/licenses/by/4.0/>

then the representation contains the following three links:

- one link of type "http://www.iana.org/assignments/relation/next" from <http://example.com/TheBook/chapter3> to <http://example.com/TheBook/chapter4>,
2.2. Links, Forms, and Metadata

In its entirety, CoRAL is an expressive language for describing Web links between resources, possible operations on these resources, and simple resource metadata. For example, if an HTTP client sends the following request:

    GET /tasks HTTP/1.1
    Host: example.com

and receives the following response:
HTTP/1.1 200 OK
Content-Type: text/coral

#using <http://example.org/vocabulary#>
#using coral = <urn:TBD#>

task </tasks/1> {
    description "Pick up the kids"
}

task </tasks/2> {
    description "Return the books to the library"
    coral:delete -> DELETE </tasks/2>
}

coral:create -> POST </tasks> [coral:accept "example/task"]

then the representation contains the following six elements:

- one link of type "http://example.org/vocabulary#task" from <http://example.com/tasks> to <http://example.com/tasks/1>,
- one link of type "http://example.org/vocabulary#description" from <http://example.com/tasks/1> to "Pick up the kids",
- one link of type "http://example.org/vocabulary#task" from <http://example.com/tasks> to <http://example.com/tasks/2>,
- one link of type "http://example.org/vocabulary#description" from <http://example.com/tasks/2> to "Return the books to the library",
- one form of type "urn:TBD#delete" that can be used to delete <http://example.com/tasks/2> by making a DELETE request to <http://example.com/tasks/2>, and
- one form of type "urn:TBD#create" that can be used to create a new item in <http://example.com/tasks> by making a POST request to <http://example.com/tasks> with an "example/task" payload.

3. Data and Interaction Model

The Constrained RESTful Application Language (CoRAL) is designed for building Web-based applications [W3C.REC-webarch-20041215] in which automated software agents navigate between resources by following links and perform operations on resources by submitting forms.
3.1. Browsing Context

Borrowing from HTML 5 [W3C.REC-html52-20171214], each such agent maintains a _browsing context_ in which the representations of Web resources are processed. (In HTML 5, the browsing context typically corresponds to a tab or window in a Web browser.)

A browsing context has a _session history_ that lists the resource representations that the agent has processed, is processing, or will process. At any time, one representation in each browsing context is designated the _active_ representation.

A session history consists of a flat list of session history entries. Each _session history entry_ consists of a resource representation and the Internationalized Resource Identifier (IRI) [RFC3987] that was used to retrieve the representation. An entry may additionally have other information associated with it. New entries are added to the session history as the agent navigates from resource to resource.

3.2. Documents

A resource representation in one of the CoRAL serialization formats is called a CoRAL _document_. The IRI that was used to retrieve such a document is called the document’s _retrieval context_.

A CoRAL document consists of a list of zero or more links, forms, and embedded resource representations, collectively called _elements_. CoRAL serialization formats may define additional types of elements for efficiency or convenience, such as base IRIs for relative IRI references.

3.3. Links

A _link_ describes a relationship between two resources on the Web [RFC8288]. As defined in RFC 8288, it consists of a _link context_, a _link relation type_, and a _link target_. In CoRAL, a link can additionally have a nested list of zero or more elements, which take the place of link target attributes.

A link can be viewed as a statement of the form "{link context} has a {link relation type} resource at {link target}" where the link target may be further described by nested elements.

The link relation type identifies the semantics of a link. In HTML 5 and the RFC 8288 Link header field, link relation types are typically denoted by an IANA-registered name, such as "stylesheet" or "icon". In CoRAL, in contrast, link relation types are denoted by an IRI or an unsigned integer. IRIs on the one hand allow for the creation of...
new, unique relation types in a decentralized fashion, but can incur a high overhead in terms of message size. Small, unsigned integers on the other hand minimize the overhead of link relation types in constrained environments, but require the assignment of values by a registry to avoid collisions.

The link context and the link target are both resources on the Web. Resources are denoted in CoRAL either by an IRI reference [RFC3987] or (similarly to RDF) a literal. If the IRI scheme indicates a Web transfer protocol such as HTTP or CoAP, then an agent can dereference the IRI and navigate the browsing context to the referenced resource; this is called _following the link_. A literal directly identifies a value, which in CoRAL can be a Boolean value, an integer, a floating-point number, a byte string, or a text string.

A link can occur as a top-level element in a document or as a nested element within a link. When a link occurs as a top-level element, the link context is implicitly the document’s retrieval context. When a link occurs nested within a link, the link context of the inner link is the link target of the outer link.

There are no restrictions on the cardinality of links; there can be multiple links to and from a particular target, and multiple links of the same or different types between a given link context and target. However, the CoRAL data model constrains the description of a resource graph to a tree: Links between linked resources can only be described by further nesting links.

3.4. Forms

A _form_ provides instructions to an agent for performing an operation on a Web resource. It consists of a _form context_, a _form relation type_, a _request method_, and a _submission IRI_. Additionally, a form may be accompanied by _form data_.

A form can be viewed as an instruction of the form "To perform a {form relation type} operation on {form context}, make a {request method} request to {submission IRI}" where the payload of the request may be further described by form data.

The form relation type identifies the semantics of the operation. Like link relation types, form relation types are denoted by an IRI or an unsigned integer.

The form context is the resource on which an operation is ultimately performed. To perform the operation, an agent needs to construct a request with the specified request method and submission IRI. The submission IRI typically refers to the form context, but MAY refer to
another resource. Constructing and sending the request is called _submitting the form_.

If a form is accompanied by form data (Section 3.5), then the agent MUST also construct a payload that matches the specifications of the form data and include that in the request.

A form can occur as a top-level element in a document or as a nested element within a link. When a form occurs as a top-level element, the form context is implicitly the document’s retrieval context. When a form occurs nested within a link, the form context is the link target of the enclosing link.

### 3.5. Form Data

Form data provides instructions for agents to construct a request payload. It consists of a list of zero or more _form fields_. Each form field consists of a _form field name_ and a _form field value_.

Form fields can either directly identify data items that need to be included in the request payload or reference another resource (such as a schema) that describes the data items. Form fields may also provide other information, such as acceptable representation formats.

The form field name identifies the semantics of the form field. Like link and form relation types, form field names are denoted by an IRI or an unsigned integer.

The form field value can be an IRI, a Boolean value, an integer, a floating-point number, a byte string, or a text string.

### 3.6. Embedded Representations

When a document contains links to many resources and an agent needs a representation of each link target, it may be inefficient to retrieve each of these representations individually. To alleviate this, documents can directly embed representations of resources.

An _embedded representation_ consists of a sequence of bytes, plus _representation metadata_ to describe those bytes.

An embedded representation may be a full, partial, or inconsistent version of the representation served from the IRI of the represented resource.

An embedded representation can occur as a top-level element in a document or as a nested element within a link. When it occurs as a top-level element, it provides an alternate representation of the
Document’s retrieval context. When it occurs nested within a link, it provides a representation of link target of the enclosing link.

3.7. Navigation

An agent begins interacting with an application by performing a GET request on an _entry point IRI_. The entry point IRI is the only IRI an agent is expected to know before interacting with an application. From there, the agent is expected to make all requests by following links and submitting forms provided by the server in responses. The entry point IRI can be obtained by manual configuration or through some discovery process.

If dereferencing the entry point IRI yields a CoRAL document or any other representation that implements the CoRAL data and interaction model, then the agent proceeds as follows:

1. The first step for the agent is to decide what to do next, i.e., which type of link to follow or form to submit, based on the link relation types and form relation types it understands.

2. The agent finds the link(s) or form(s) with the respective relation type in the active representation. This may yield one or more candidates, from which the agent must select the most appropriate one in the next step. The set of candidates may be empty, for example, when a transition is not supported or not allowed.

3. The agent selects one of the candidates based on the metadata associated with the link(s) or form(s). Metadata typically includes the media type of the target resource representation, the IRI scheme, the request method, and other information that is provided as nested elements in a link and form data in a form.

   If the selected candidate contains an embedded representation, then the agent MAY skip the following steps and immediately proceed with step 8.

4. The agent resolves the IRI reference in the link or form (Section 5 of RFC 3986 [RFC3986]) to obtain the _request IRI_. Fragment identifiers are not part of the request IRI and MUST be separated from the rest of the IRI prior to a dereference. The request IRI may need to be converted to a URI (Section 3.1 of RFC 3987 [RFC3987]) for protocols that do not support IRIs.

5. The agent constructs a new request with the request IRI. If the agent follows a link, the request method MUST be GET. If the agent submits a form, the request method MUST be the one
specified in the form. The agent SHOULD set HTTP header fields and CoAP request options according to provided metadata (e.g., set the HTTP Accept header field or the CoAP Accept option when the media type of the target resource is provided). In case of a form with form data, the agent MUST also include a request payload that matches the specifications of the form data.

6. The agent sends the request and receives the response.

7. If a fragment identifier was separated from the request IRI, the agent dereferences the fragment identifier within the received representation.

8. The agent _updates the session history_: It removes all the entries in the browsing context’s session history after the current entry. Then it appends a new entry at the end of the history representing the new resource and makes that entry the active representation.

9. Finally, the agent processes the representation. In case of a CoRAL document or any other representation that implements the CoRAL data and interaction model, this means the agent decides again what to do next -- and the cycle repeats.

3.8. History Traversal

An agent can navigate a browsing context also by traversing the browsing context’s session history. An agent can _traverse the session history_ by updating the active representation to the that entry.

4. Binary Format

This section defines the encoding of documents in the CoRAL binary format.

A document in the binary format is a data item in Concise Binary Object Representation (CBOR) [RFC7049]. The structure of this data item is presented in the Concise Data Definition Language (CDDL) [I-D.ietf-cbor-cddl]. The media type is "application/coral+cbor".

4.1. Data Structure

The data structure of a document in the binary format is made up of four kinds of elements: links, forms, embedded representations, and (as an extension to the CoRAL data model) base IRI directives. Base IRI directives provide a way to encode IRI references with a common base more efficiently.
Elements are processed in the order they appear in the document. Document processors need to maintain an _environment_ while iterating an array of elements. The environment consists of three variables: a _current context IRI_, a _current base IRI_, and a _current relation type_. The current context IRI and current base IRI are initially both set to the document’s retrieval context. The current relation type is initially set to the unsigned integer zero.

### 4.1.1. Documents

The body of a document in the binary format is encoded as an array of zero or more links, forms, embedded representations, and directives.

\[\text{body} = \{\text{link} / \text{form} / \text{representation} / \text{directive}\}\]

### 4.1.2. Links

A link is encoded as an array that consists of the unsigned integer 2, followed by the link relation type and the link target, optionally followed by a link body that contains nested elements.

\[\text{link} = \{\text{link: 2}, \text{relation}, \text{target}, \text{?body}\}\]

The link relation type is encoded either as a text string containing an absolute IRI reference or as an (unsigned or negative) integer representing the difference to the current relation type. A link is processed by updating the current relation type to the result of adding the specified integer (or zero in the case of a text string) to the current relation type. It is an error if the current relation type becomes negative.

\[\text{relation} = \text{text} / \text{int}\]

The link target is denoted by an IRI reference or represented by a literal value. The IRI reference MAY be relative or absolute, and MUST be resolved against the current base IRI. The encoding of IRI references in the binary format is described in RFC XXXX [I-D.hartke-t2trg-ciri]. The link target MAY be null, which indicates that the link target is an unidentified resource.

\[\text{target} = \text{ciri} / \text{literal} / \text{null}\]

\[\text{literal} = \text{bool} / \text{int} / \text{float} / \text{bytes} / \text{text}\]

The array of elements in the link body, if any, MUST be processed in a fresh environment. The current context IRI and current base IRI in the new environment are initially both set to the link target of the
enclosing link. The current relation type in the new environment is initially set to the current relation type.

4.1.3. Forms

A form is encoded as an array that consists of the unsigned integer 3, followed by the form relation type, the submission method, and a submission IRI reference, optionally followed by form data.

\[
\text{form} = [\text{form: 3, relation, method, ciri, ?form-data}]
\]

The form relation type is encoded and processed in the same way as a link relation type (Section 4.1.2).

The method MUST refer to one of the request methods defined by the Web transfer protocol identified by the scheme of the submission IRI. It is encoded either as a text string or an unsigned integer.

\[
\text{method} = \text{text / uint}
\]

For HTTP [RFC7230], the method MUST be encoded as a text string in the format defined in Section 4.1 of RFC 7231 [RFC7231]; the set of possible values is maintained in the IANA HTTP Method Registry. For CoAP [RFC7252], the method MUST be encoded as an unsigned integer (e.g., the unsigned integer 2 for the POST method); the set of possible values is maintained in the IANA CoAP Method Codes Registry.

The submission IRI reference MAY be relative or absolute, and MUST be resolved against the current base IRI. The encoding of IRI references in the binary format is described in RFC XXXX [I-D.hartke-t2trg-ciri].

4.1.3.1. Form Data

Form data is encoded as an array of zero or more name-value pairs.

\[
\text{form-data} = [*(\text{form-field-name, form-field-value})]
\]

Form data, if any, MUST be processed in a fresh environment. The current context IRI and current base IRI in the new environment are initially both set to the submission IRI of the enclosing form. The current relation type in the new environment is initially set to the current relation type.

A form field name is encoded and processed in the same way as a link relation type (Section 4.1.2).

\[
\text{form-field-name} = \text{text / uint}
\]
A form field value can be an IRI reference, a Boolean value, an integer, a floating-point number, a byte string, a text string, or null. An IRI reference MAY be relative or absolute, and MUST be resolved against the current base IRI. The encoding of IRI references in the binary format is described in RFC XXXX [I-D.hartke-t2trg-ciri].

form-field-value = ciri / bool / int / float / bytes / text / null

4.1.3.2. Short Forms

Forms in certain shapes can be encoded in a more efficient manner using short forms. The following short forms are available:

form /= [form.create: 4, ?accept: uint .size 2]
form /= [form.update: 5, ?accept: uint .size 2]
form /= [form.delete: 6]
form /= [form.search: 7, ?accept: uint .size 2]

If the scheme of the submission IRI indicates HTTP, the short forms expand as follows:

[4, x]  ->  [3, "urn:TBD#create", "POST", [],
                ["urn:TBD#accept", x]]
[5, x]  ->  [3, "urn:TBD#update", "PUT", [],
                ["urn:TBD#accept", x]]
[7, x]  ->  [3, "urn:TBD#search", "POST", [],
                ["urn:TBD#accept", x]]

If the scheme of the submission IRI indicates CoAP, the short forms expand as follows (the only difference being the request methods):
The form relation types and form field names used in these expansions are defined in Appendix A.

4.1.4. Embedded Representations

An embedded representation is encoded as an array that consists of the unsigned integer 0, followed by the HTTP content type or CoAP content format of the representation and a byte string containing the representation data.

representation = [representation: 0, text / uint, bytes]

For HTTP, the content type MUST be specified as a text string in the format defined in Section 3.1.1.1 of RFC 7231 [RFC7231]; the set of possible values is maintained in the IANA Media Types Registry. For CoAP, the content format MUST be specified as an unsigned integer; the set of possible values is maintained in the IANA CoAP Content-Formats Registry.

4.1.5. Directives

Directives provide the ability to manipulate the environment when processing a list of elements. There is one directive available: the Base IRI directive.

directive = base-directive

4.1.5.1. Base IRI Directives

A Base IRI directive is encoded as an array that consists of the negative integer -1, followed by an IRI reference.

base-directive = [base: -1, ciri]

The IRI reference MAY be relative or absolute, and MUST be resolved against the current context IRI. The encoding of IRI references in the binary format is described in RFC XXXX [I-D.hartke-t2trg-ciri].
The directive is processed by resolving the IRI reference against the current context IRI and assigning the result to the current base IRI.

5. Textual Format

This section defines the syntax of documents in the CoRAL textual format using two grammars: The lexical grammar defines how Unicode characters are combined to form line terminators, white space, comments, and tokens. The syntactic grammar defines how the tokens are combined to form documents. Both grammars are presented in Augmented Backus-Naur Form (ABNF) [RFC5234].

A document in the textual format is a Unicode string in a Unicode encoding form [UNICODE]. The media type for such documents is "text/coral". The "charset" parameter is not used; charset information is transported inside the document in the form of an OPTIONAL Byte Order Mark (BOM). The use of the UTF-8 encoding scheme [RFC3629], without a BOM, is RECOMMENDED.

5.1. Lexical Structure

The lexical structure of a document in the textual format is made up of four basic elements: line terminators, white space, comments, and tokens. Of these, only tokens are significant in the syntactic grammar. There are four kinds of tokens: identifiers, IRI references, literals, and punctuators.

When several lexical grammar rules match a sequence of characters in a document, the longest match takes priority.

5.1.1. Line Terminators

Line terminators divide text into lines. A line terminator is any Unicode character with Line_Break class BK, CR, LF, or NL. However, any CR character that immediately precedes a LF character is ignored. (This affects only the numbering of lines in error messages.)

5.1.2. White Space

White space is a sequence of one or more white space characters. A white space character is any Unicode character with the White_Space property.

5.1.3. Comments

Comments are sequences of characters that are ignored when parsing text into tokens. Single-line comments begin with the characters "//" and extend to the end of the line. Delimited comments begin
with the characters "/*/" and end with the characters "/". Delimited comments can occupy a portion of a line, a single line, or multiple lines.

Comments do not nest. The character sequences "//*" and "/*/" have no special meaning within a single-line comment; the character sequences "///" and "/*/" have no special meaning within a delimited comment.

5.1.4. Identifiers

An identifier tokens is a user-defined symbolic name. The rules for identifiers correspond to those recommended by the Unicode Standard Annex #31 [UNICODE-UAX31] using the following profile:

```
identifier = start *continue *(medial 1*continue)
start = <Any character with the XID_Start property>
continue = <Any character with the XID_Continue property>
medial = "-" / "." / "/" / %xB7 / %x58A / %xF0B
medial /= %x2010 / %x2027 / %x30A0 / %x30FB
```

All identifiers MUST be converted into Unicode Normalization Form C (NFC), as defined by the Unicode Standard Annex #15 [UNICODE-UAX15]. Comparison of identifiers is based on NFC and is case-sensitive (unless otherwise noted).

5.1.5. IRI References

An IRI reference is a Unicode string that conforms to the syntax defined in RFC 3987 [RFC3987]. An IRI reference can be absolute or relative, and can contain a fragment identifier. IRI references are enclosed in angle brackets ("<" and ">").

```
iri = "<" IRI-reference ">"

IRI-reference = <Defined in Section 2.2 of RFC 3987>
```

5.1.6. Literals

A literal is a textual representation of a value. There are six types of literals: Boolean, integer, floating-point, byte string, text string, and null.
5.1.6.1. Boolean Literals

The case-insensitive tokens "true" and "false" denote the Boolean values true and false, respectively.

boolean = "true" / "false"

5.1.6.2. Integer Literals

Integer literals denote integer values of unspecified precision. By default, integer literals are expressed in decimal, but they can also be specified in an alternate base using a prefix. Binary literals begin with "0b", octal literals begin with "0o", and hexadecimal literals begin with "0x".

Decimal literals contain the digits "0" through "9". Binary literals contain "0" and "1", octal literals contain "0" through "7", and hexadecimal literals contain "0" through "9" as well as "A" through "F" in upper- or lowercase.

Negative integers are expressed by prepending a minus sign ("-").

integer = ["+" / "-"] (decimal / binary / octal / hexadecimal)

decimal = 1*DIGIT

binary = %x30 (%x42 / %x62) 1*BINDIG

octal = %x30 (%x4F / %x6F) 1*OCTDIG

hexadecimal = %x30 (%x58 / %x78) 1*HEXDIG

DIGIT = %x30-39

BINDIG = %x30-31

OCTDIG = %x30-37

HEXDIG = %x30-39 / %x41-46 / %x61-66

5.1.6.3. Floating-point Literals

Floating-point literals denote floating-point numbers of unspecified precision.

Floating-point literals consist of a sequence of decimal digits followed by a fraction, an exponent, or both. The fraction consists of a decimal point (".") followed by a sequence of decimal digits.
The exponent consists of the letter "e" in upper- or lowercase, followed by an optional sign and a sequence of decimal digits that indicate a power of 10 by which the value preceding the "e" is multiplied.

Negative floating-point values are expressed by prepending a minus sign ("-").

\[
\text{floating-point} = \left[\text{"+"} / \text{"-"}\right] 1\text{DIGIT} \text{[fraction]} \text{[exponent]}
\]

\[
\text{fraction} = \text{"."} 1\text{DIGIT}
\]

\[
\text{exponent} = (\%x45 / \%x65) \left[\text{"+"} / \text{"-"}\right] 1\text{DIGIT}
\]

Floating-point literals can additionally denote the special "Not-a-Number" (NaN) value, positive infinity, and negative infinity. The NaN value is produced by the case-insensitive token "NaN". The two infinite values are produced by the case-insensitive tokens "+Infinity" (or simply "Infinity") and "-Infinity".

\[
\text{floating-point} =/ \text{"NaN"}
\]

\[
\text{floating-point} =/ \left[\text{"+"} / \text{"-"}\right] \text{"Infinity"}
\]

### 5.1.6.4. Byte String Literals

A byte string literal consists of a prefix and zero or more bytes encoded in Base16, Base32, or Base64 [RFC4648] and enclosed in single quotes. Byte string literals encoded in Base16 begin with "h" or "b16", byte string literals encoded in Base32 begin with "b32", and byte string literals encoded in Base64 begin with "b64".

\[
\text{bytes} = \text{base16} / \text{base32} / \text{base64}
\]

\[
\text{base16} = (\%x68 / \%x62.31.36) \text{SQUOTE <Base16 encoded data> SQUOTE}
\]

\[
\text{base32} = \%x62.33.32 \text{SQUOTE <Base32 encoded data> SQUOTE}
\]

\[
\text{base64} = \%x62.36.34 \text{SQUOTE <Base64 encoded data> SQUOTE}
\]

\[
\text{SQUOTE} = \%x27
\]

### 5.1.6.5. Text String Literals

A text string literal consists of zero or more Unicode characters enclosed in double quotes. It can include simple escape sequences (such as \t for the tab character) as well as hexadecimal and Unicode escape sequences.
text = DQUOTE *(char / %x5C escape) DQUOTE
char = <Any character except %x22, %x5C, and line terminators>
escape = simple-escape / hexadecimal-escape / unicode-escape
simple-escape = %x30 / %x62 / %x74 / %x6E / %x76
simple-escape =/ %x66 / %x72 / %x22 / %x27 / %x5C
hexadecimal-escape = (%x78 / %x58) 2HEXDIG
unicode-escape = %x75 4HEXDIG / %x55 8HEXDIG
DQUOTE = %x22

An escape sequence denotes a single Unicode code point. For hexadecimal and Unicode escape sequences, the code point is expressed by the hexadecimal number following the "\x", "\X", "\u", or "\U" prefix. Simple escape sequences indicate the code points listed in Table 1.

<table>
<thead>
<tr>
<th>Escape Sequence</th>
<th>Code Point</th>

</tr>
</tbody>
</table>

Table 1: Simple Escape Sequences

5.1.6.6. Null Literal

The case-insensitive tokens "null" and "_" denote the intentional absence of any value.

null = "null" / "_"
5.1.7. Punctuators

Punctuator tokens are used for grouping and separating.

\[
punctuator = \# | \:: | \* | [ | ] | \{ | \} | = | \rightarrow
\]

5.2. Syntactic Structure

The syntactic structure of a document in the textual format is made up of four kinds of elements: links, forms, embedded representations, and (as an extension to the CoRAL data model) directives. Directives provide a way to make documents easier to read and write by defining base IRIs for relative IRI references and introducing shorthands for IRIs.

Elements are processed in the order they appear in the document. Document processors need to maintain an _environment_ while iterating a list of elements. The environment consists of three variables: a _current context IRI_, a _current base IRI_, and a _current mapping from identifiers to IRIs_. The current context IRI and current base IRI are initially both set to the document’s retrieval context. The current mapping from identifiers to IRIs is initially empty.

5.2.1. Documents

The body of a document in the textual format consists of zero or more links, forms, and directives.

\[
body = *(link / form / representation / directive)
\]

5.2.2. Links

A link consists of the link relation type, followed by the link target, optionally followed by a link body enclosed in curly brackets ({" and "}).

\[
link = relation target ["{" body "}"]
\]

The link relation type is denoted either by an absolute IRI reference, a simple name, a qualified name, or an integer.

\[
relation = iri / simple-name / qualified-name / integer
\]

A simple name consists of an identifier. It is resolved to an IRI by looking up the empty string in the current mapping from identifiers to IRIs and appending the specified identifier to the result. It is an error if the empty string is not present in the mapping.
simple-name = identifier

A qualified name consists of two identifiers separated by a colon (":"). It is resolved to an IRI by looking up the identifier on the left hand side in the current mapping from identifiers to IRIs and appending the identifier on the right hand side to the result. It is an error if the identifier on the left hand side is not present in the mapping.

qualified-name = identifier ":" identifier

The link target is denoted by an IRI reference or represented by a value literal. The IRI reference MAY be relative or absolute, and MUST be resolved against the current base IRI. If the link target is null, the link target is an unidentified resource.

target = iri / literal / null

literal = boolean / integer / floating-point / bytes / text

The list of elements in the link body, if any, MUST be processed in a fresh environment. The current context IRI and current base IRI in this environment are initially both set to the link target of the enclosing link. The mapping from identifiers to IRIs is initially set to a copy of the mapping from identifiers to IRIs in the current environment.

5.2.3. Forms

A form consists of the form relation type, followed by a "->" token, a method identifier, and a submission IRI reference, optionally followed by form data enclosed in square brackets ("[" and "]").

form = relation "->" method iri ["[" form-data "]"]

The form relation type is denoted in the same way as a link relation type (Section 5.2.2).

The method identifier refers to one of the request methods defined by the Web transfer protocol identified by the scheme of the submission IRI. Method identifiers are case-insensitive and constrained to Unicode characters in the Basic Latin block.

method = identifier

For HTTP [RFC7230], the set of possible method identifiers is maintained in the IANA HTTP Method Registry. For CoAP [RFC7252], the
set of possible method identifiers is maintained in the IANA CoAP
Method Codes Registry.

The submission IRI reference MAY be relative or absolute, and MUST be
resolved against the current base IRI.

5.2.3.1. Form Data

Form data consists of zero or more name-value pairs.

    form-data = *(form-field-name form-field-value)

Form data, if any, MUST be processed in a fresh environment. The
current context IRI and current base IRI in this environment are
initially both set to the submission IRI of the enclosing form. The
mapping from identifiers to IRIs is initially set to a copy of the
mapping from identifiers to IRIs in the current environment.

The form field name is denoted in the same way as a link relation
type (Section 5.2.2).

    form-field-name = iri / simple-name / qualified-name / integer

The form field value can be an IRI reference, Boolean literal,
integer literal, floating-point literal, byte string literal, text
string literal, or null. An IRI reference MAY be relative or
absolute, and MUST be resolved against the current base IRI.

    form-field-value = iri / boolean / integer
    form-field-value = floating-point / bytes / text / null

5.2.4. Embedded Representations

An embedded representation consists of a "*" token, followed by the
representation data, optionally followed by representation metadata
enclosed in square brackets ("[" and "]").

    representation = "*" bytes ["[" representation-metadata "]"]

Representation metadata consists of zero or more name-value pairs.

    representation-metadata = *(metadata-name metadata-value)

This document specifies only one kind of metadata item, labeled with
the name "type": the HTTP content type or CoAP content format of the
representation.
metadata-name = "type"
metadata-value = text / integer

For HTTP, the content type MUST be specified as a text string in the format defined in Section 3.1.1.1 of RFC 7231 [RFC7231]; the set of possible values is maintained in the IANA Media Types Registry. For CoAP, the content format MUST be specified as an integer; the set of possible values is maintained in the IANA CoAP Content-Formats Registry.

A metadata item with the name "type" MUST NOT occur more than once. If absent, its value defaults to content type "application/octet-stream" or content format 42.

5.2.5. Directives

Directives provide the ability to manipulate the environment when processing a list of elements. All directives start with a number sign ("#") followed by a directive identifier. Directive identifiers are case-insensitive and constrained to Unicode characters in the Basic Latin block.

The following directives are available: Base IRI directives and Using directives.

   directive = base-directive / using-directive

5.2.5.1. Base IRI Directives

A Base IRI directive consists of a number sign ("#"), followed by the case-insensitive identifier "base", followed by an IRI reference.

   base-directive = "#" "base" iri

The IRI reference MAY be relative or absolute, and MUST be resolved against the current context IRI.

The directive is processed by resolving the IRI reference against the current context IRI and assigning the result to the current base IRI.

5.2.5.2. Using Directives

A Using directive consists of a number sign ("#"), followed by the case-insensitive identifier "using", optionally followed by an identifier and an equals sign ("="), finally followed by an absolute IRI reference. If the identifier is not specified, it is assumed to be the empty string.
using-directive = "#" "using" [identifier "="] iri

The IRI reference MUST be absolute.

The directive is processed by adding the specified identifier and IRI to the current mapping from identifiers to IRIs. It is an error if the identifier is already present in the mapping.

6. Usage Considerations

This section discusses some considerations in creating CoRAL-based applications and managing link and form relation types.

6.1. Specifying CoRAL-based Applications

CoRAL-based applications naturally implement the Web architecture [W3C.REC-webarch-20041215] and thus are centered around orthogonal specifications for identification, interaction, and representation:

- Resources are identified by IRIs or represented by value literals.
- Interactions are based on the hypermedia interaction model of the Web and the methods provided by the Web transfer protocol. The semantics of possible interactions are identified by link and form relation types.
- Representations are CoRAL documents encoded in the binary format defined in Section 4 or the textual format defined in Section 5. Depending on the application, additional representation formats may be used.

Specifications for CoRAL-based applications need to list the specific components used in the application and their identifiers. This SHOULD include at least the following items:

- IRI schemes that identify the Web transfer protocol(s) used in the application.
- Internet media types that identify the representation format(s) used in the application, including the media type(s) of the CoRAL serialization format(s).
- Link relation types that identify the semantics of links.
- Form relation types that identify the semantics of forms. Additionally, for each form relation type, the permissible request method(s).
Form field names that identify the semantics of form fields. Additionally, for each form field name, the permissible form field value(s) or type(s).

6.1.1. Naming Resources

Resource names -- URIs [RFC3986] and IRIs [RFC3987] -- are a cornerstone of Web-based applications. They enable the uniform identification of resources and are used every time a client interacts with a server or a resource representation needs to refer to another resource.

URIs and IRIs often include structured application data in the path and query components, such as paths in a filesystem or keys in a database. It is a common practice in many HTTP-based applications to make this part of the application specification, i.e., to prescribe fixed URI templates that are hard-coded in implementations. There are, however, a number of problems with this practice [RFC7320].

In CoRAL-based applications, resource names are not part of the application specification; they are an implementation detail. The specification of a CoRAL-based application MUST NOT mandate any particular form of resource name structure. BCP 190 [RFC7320] describes the problematic practice of fixed URI structures in more detail and provides some acceptable alternatives.

6.1.2. Implementation Limits

This document places no restrictions on the number of elements in a CoRAL document or the depth of nested elements. Applications using CoRAL (in particular those running in constrained environments) MAY wish to limit these numbers and specify implementation limits that an application implementation must at least support to be interoperable.

Applications MAY also mandate the following and other restrictions:

- use of only either the binary format or the text format;
- use of only either HTTP or CoAP as supported Web transfer protocol;
- use of only either IRIs or unsigned integers to denote link relation types, form relation types, and form field names;
- use of only either short forms or long forms in the binary format;
- use of only either HTTP content types or CoAP content formats;
o use of IRI references only up to a specific length;
o use of CBOR in a canonical format (Section 3.9 of RFC 7049 [RFC7049]).

### 6.2. Minting New Relation Types

New link relation types, form relation types, and form field names can be minted by defining an IRI [RFC3987] that uniquely identifies the item. Although the IRI can point to a resource that contains a definition of the semantics of the relation type, clients SHOULD NOT automatically access that resource to avoid overburdening its server. The IRI SHOULD be under the control of the person or party defining it, or be delegated to them.

Link relation types registered in the IANA Link Relations Registry, such as "collection" [RFC6573] or "icon" [W3C.REC-html52-20171214], can be used in CoRAL by appending the registered name to the IRI `<http://www.iana.org/assignments/relation/>`:

```
#using iana = <http://www.iana.org/assignments/relation/>
iana:collection </items>
iana:icon       </favicon.png>
```

A good source for link relation types for resource metadata are RDF predicates [W3C.REC-rdf11-concepts-20140225]. An RDF statement says that some relationship, indicated by a predicate, holds between two resources. RDF predicates and link relation types can therefore often be used interchangeably. For example, a CoRAL document could describe its creator by using the FOAF vocabulary [FOAF]:

```
#using iana = <http://www.iana.org/assignments/relation/>
#using foaf = <http://xmlns.com/foaf/0.1/>

foaf:maker _ {
  iana:type       <http://xmlns.com/foaf/0.1/Person>
  foaf:familyName "Hartke"
  foaf:givenName  "Klaus"
  foaf:mbox       <mailto:klaus.hartke@ericsson.com>
}
```

### 6.3. Registering Relation Types

IRIs that identify link relation types, form relation types, and form field names do not need to be registered. The inclusion of DNS names in IRIs allows for the decentralized creation of new IRIs without the risk of collisions.
However, IRIs can be relatively verbose and impose a high overhead on representations. This can be a problem in constrained environments [RFC7228]. Therefore, CoRAL alternatively allows the use of unsigned integers to identify link relation types, form relation types, and form field names. These impose a much smaller overhead but instead need to be assigned by a registry to avoid collisions.

This document does not create a registry for such integers. Instead, the media types for CoRAL documents in the binary and textual format are defined to have a "profile" parameter [RFC6906] that determines the registry in use. The registry is identified by a URI [RFC3986]. For example, a CoRAL document that uses the registry identified by the URI <http://example.com/registry> can use the following media type:

```
application/coral+cbor; profile="http://example.com/registry"
```

The URI serves only as an identifier; it does not necessarily have to be dereferencable (or even use a dereferencable URI scheme). It is permissible, though, to use a dereferencable URI and to serve a representation that provides information about the registry in a human- or machine-readable way. (The format of such a representation is outside the scope of this document.)

For simplicity, a CoRAL document can use unsigned integers from only one registry. The "profile" parameter of the CoRAL media types MUST contain a single URI, not a white space separated list of URIs as recommended by RFC 6906 [RFC6906]. If the "profile" parameter is absent, the default profile specified in Appendix B of this document is assumed.

A CoRAL registry SHOULD map each unsigned integer to a full IRI that identifies a link relation type, form relation type, or form field name. Once an integer has been assigned, the assignment MUST NOT be changed or removed. A registry MAY provide additional information about an assignment that MAY change over time.

In CoAP [RFC7252], media types (including specific values for their parameters) are encoded as an unsigned integer called the _content format_. For use with CoAP, each CoRAL registry needs to register a new content format in the IANA CoAP Content-Formats Registry. Each such registered content format MUST specify a CoRAL media type with a "profile" parameter that contains the registry URI.
6.4. Expressing Link Target Attributes

Link target attributes defined for use with CoRE Link Format [RFC6690] (such as "type", "hreflang", "media", "ct", "rt", "if", "sz", and "obs") can be expressed in CoRAL by nesting links under the respective link and specifying the attribute name appended to the IRI <http://TBD/> as the link relation type.

If the expressed link target attribute has a value, the target of the nested link MUST be a text string; otherwise, the target MUST be the Boolean value "true":

```plaintext
#using iana = <http://www.iana.org/assignments/relation/>
#using attr = <http://TBD/>

iana:item </patches/1> {
    attr:type "application/json-patch+json"
    attr:ct   "51"
    attr:sz   "247"
    attr:obs  true
}
```

[[NOTE TO RFC EDITOR: Please replace all occurrences of "http://TBD/"]
 in this document with an IETF-controlled IRI, such as "urn:ietf:..." or "http://...ietf.org/...".]]

Link target attributes that do not actually describe the link target but the link itself (such as "rel", "anchor", "rev", "title", and "title*") are excluded from this provision and MUST NOT occur in a CoRAL document.

6.5. Embedding CoRAL in CBOR Structures

Data items in the CoRAL binary format (Section 4) MAY be embedded in other CBOR [RFC7049] data structures. Specifications using CDDL [I-D.ietf-cbor-cddl] SHOULD reference the following CDDL definitions for this purpose:

```plaintext
CoRAL-Body = body

CoRAL-Link = link

CoRAL-Form = form
```
7. Security Considerations

Parsers of CoRAL documents must operate on input that is assumed to be untrusted. This means that parsers MUST fail gracefully in the face of malicious inputs. Additionally, parsers MUST be prepared to deal with resource exhaustion (e.g., resulting from the allocation of big data items) or exhaustion of the call stack (stack overflow). See Section 8 of RFC 7049 [RFC7049] for security considerations relating to parsing CBOR.

Implementers of the CoRAL textual format need to consider the security aspects of handling Unicode input. See the Unicode Standard Annex #36 [UNICODE-UAX36] for security considerations relating to visual spoofing and misuse of character encodings. See Section 10 of RFC 3629 [RFC3629] for security considerations relating to UTF-8.

CoRAL makes extensive use of IRIs and URIs. See Section 8 of RFC 3987 [RFC3987] for security considerations relating to IRIs. See Section 7 of RFC 3986 [RFC3986] for security considerations relating to URIs.

The security of applications using CoRAL can depend on the proper preparation and comparison of internationalized strings. For example, such strings can be used to make authentication and authorization decisions, and the security of an application could be compromised if an entity providing a given string is connected to the wrong account or online resource based on different interpretations of the string. See RFC 6943 [RFC6943] for security considerations relating to identifiers in IRIs and other locations.

CoRAL is intended to be used in conjunction with a Web transfer protocol like HTTP or CoAP. See Section 9 of RFC 7320 [RFC7320], Section 9 of RFC 7231 [RFC7231], etc., for security considerations relating to HTTP. See Section 11 of RFC 7252 [RFC7252] for security considerations relating to CoAP.

CoRAL does not define any specific mechanisms for protecting the confidentiality and integrity of CoRAL documents. It relies on application layer or transport layer mechanisms for this, such as Transport Layer Security (TLS) [RFC8446].

CoRAL documents and the structure of a web of resources revealed from automatically following links can disclose personal information and other sensitive information. Implementations need to prevent the unintentional disclosure of such information. See Section of 9 of RFC 7231 [RFC7231] for additional considerations.
Applications using CoRAL ought to consider the attack vectors opened by automatically following, trusting, or otherwise using links and forms in CoRAL documents. In particular, a server that is authoritative for the CoRAL representation of a resource may not necessarily be authoritative for elements nested inside the top level links in the document.

8. IANA Considerations

8.1. Media Type "application/coral+cbor"

This document registers the media type "application/coral+cbor" according to the procedures of BCP 13 [RFC6838].

Type name:
application

Subtype name:
coral+cbor

Required parameters:
N/A

Optional parameters:
profile - See Section 6.3 of [I-D.hartke-t2trg-coral].

Encoding considerations:
binary - See Section 4 of [I-D.hartke-t2trg-coral].

Security considerations:
See Section 7 of [I-D.hartke-t2trg-coral].

Interoperability considerations:
N/A

Published specification:
[I-D.hartke-t2trg-coral]

Applications that use this media type:
See Section 1 of [I-D.hartke-t2trg-coral].

Fragment identifier considerations:
As specified for "application/cbor".

Additional information:
Deprecated alias names for this type: N/A
Magic number(s): N/A
File extension(s): N/A
8.2. Media Type "text/coral"

This document registers the media type "text/coral" according to the procedures of BCP 13 [RFC6838] and guidelines in RFC 6657 [RFC6657].

Type name:
   text

Subtype name:
   coral

Required parameters:
   N/A

Optional parameters:
   profile - See Section 6.3 of [I-D.hartke-t2trg-coral].

Encoding considerations:
   binary - See Section 5 of [I-D.hartke-t2trg-coral].

Security considerations:
   See Section 7 of [I-D.hartke-t2trg-coral].

Interoperability considerations:
   N/A

Published specification:
   [I-D.hartke-t2trg-coral]
Applications that use this media type:
See Section 1 of [I-D.hartke-t2trg-coral].

Fragment identifier considerations:
N/A

Additional information:
Deprecated alias names for this type: N/A
Magic number(s): N/A
File extension(s): .coral
Macintosh file type code(s): TEXT

Person & email address to contact for further information:
See the Author’s Address section of [I-D.hartke-t2trg-coral].

Intended usage:
COMMON

Restrictions on usage:
N/A

Author:
See the Author’s Address section of [I-D.hartke-t2trg-coral].

Change controller:
IESG

Provisional registration?
No

8.3. CoAP Content Formats

This document registers CoAP content formats for the media types
"application/coral+cbor" and "text/coral" according to the procedures
of RFC 7252 [RFC7252].

- Media Type: application/coral+cbor
  Content Coding: identity
  ID: TBD (maybe 63)
  Reference: [I-D.hartke-t2trg-coral]

- Media Type: text/coral
  Content Coding: identity
  ID: TBD (maybe 10063)
  Reference: [I-D.hartke-t2trg-coral]
9. References

9.1. Normative References

[I-D.hartke-t2trg-ciri]
Hartke, K., "Constrained Internationalized Resource Identifiers", draft-hartke-t2trg-ciri-00 (work in progress), October 2018.

[I-D.ietf-cbor-cddl]

Note that this reference is to the latest version of Unicode, rather than to a specific release. It is not expected that future changes in the Unicode specification will have any impact on this document.

9.2. Informative References

Appendix A. Core Vocabulary

This section defines the core vocabulary for CoRAL. It is RECOMMENDED that all CoRAL registries assign an unsigned integer to each of these link relation types, form relation types, and form field names.
A.1. Link Relation Types

<http://www.iana.org/assignments/relation/type>
Indicates that the link’s context is an instance of the type specified as the link’s target; see Section 6 of RFC 6903 [RFC6903].

This link relation type serves in CoRAL the same purpose as the RDF predicate identified by the IRI <http://www.w3.org/1999/02/22-rdf-syntax-ns#type>.

<http://www.iana.org/assignments/relation/item>
Indicates that the link’s context is a collection and that the link’s target is a member of that collection; see Section 2.1 of RFC 6573 [RFC6573].

<http://www.iana.org/assignments/relation/collection>
Indicates that the link’s target is a collection and that the link’s context is a member of that collection; see Section 2.2 of RFC 6573 [RFC6573].

A.2. Form Relation Types

<urn:TBD#create>
Indicates that the form’s context is a collection and that a new item can be created in that collection by submitting a suitable representation. This form relation type is typically used with the POST method [RFC7231] [RFC7252].

<urn:TBD#update>
Indicates that the form’s context can be updated by submitting a suitable representation. This form relation type is typically used with the PUT method [RFC7231] [RFC7252], PATCH method [RFC5789] [RFC8132], or iPATCH method [RFC8132].

<urn:TBD#delete>
Indicates that the form’s context can be deleted. This form relation type is typically used with the DELETE method [RFC7231] [RFC7252].

<urn:TBD#search>
Indicates that the form’s context can be searched by submitting a search query. This form relation type is typically used with the POST method [RFC7231] [RFC7252] or FETCH method [RFC8132].
A.3. Form Field Names

<urn:TBD#accept>
Specifies an acceptable HTTP content type or CoAP content format for the request payload. There MAY be multiple form fields with this name. If a form does not include a form field with this name, the server accepts any or no request payload, depending on the form relation type.

For HTTP, the content type MUST be specified as a text string in the format defined in Section 3.1.1.1 of RFC 7231 [RFC7231]; the set of possible values is maintained in the IANA Media Types Registry. For CoAP, the content format MUST be specified as an unsigned integer; the set of possible values is maintained in the IANA CoAP Content-Formats Registry.

Appendix B. Default Profile

This section defines a default registry that is assumed when a CoRAL media type without a "profile" parameter is used.

0 = <http://www.iana.org/assignments/relation/type>
1 = <http://www.iana.org/assignments/relation/item>
2 = <http://www.iana.org/assignments/relation/collection>
3 = <urn:TBD#create>
4 = <urn:TBD#update>
5 = <urn:TBD#delete>
6 = <urn:TBD#search>
7 = <urn:TBD#accept>
