ALTO Extension: Entity Property Maps  
draft-ietf-alto-unified-props-new-17

Abstract

This document extends the base Application-Layer Traffic Optimization (ALTO) Protocol by generalizing the concept of "endpoint properties" as applied to endpoints as defined by IP addresses to endpoints defined by a wider set of objects. Further, these properties are presented as maps, similar to the network and cost maps in the base ALTO protocol. The protocol is extended in two major directions. First, from endpoints restricted to IP addresses to entities covering a wider and extensible set of objects; second, from properties on specific endpoints to entire entity property maps. These extensions introduce additional features allowing entities and property values to be specific to a given information resource. This is made possible by a generic and flexible design of entity and property types.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of [BCP 78](#) and [BCP 79](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <https://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on 18 October 2021.

## 1. Introduction

The ALTO protocol [[RFC7285](#)] introduces the concept of "properties" attached to "endpoint addresses", and defines the Endpoint Property Service (EPS) to allow ALTO clients to retrieve those properties. While useful, the EPS, as defined in [[RFC7285](#)], has at least three limitations.

First, the EPS allows properties to be associated with only endpoints that are identified by individual communication addresses like IPv4 and IPv6 addresses. It is reasonable to think that collections of endpoints, as defined by CIDRs [[RFC4632](#)] or PIDs, may also have properties. Furthermore, recent ALTO use cases show that properties of entities such as network flows [[RFC7011](#)] and routing elements [[RFC7921](#)] are also useful. Such cases are documented in [[I-D.gao-alto-fcs](#)]. The current EPS however is restricted to individual endpoints and cannot be applied to those entities.

Second, the EPS only allows endpoints identified by global communication addresses. However, an endpoint address may be a local IP address or an anycast IP address that may not be globally unique. Additionally, an entity such as a PID may have an identifier that is not globally unique. That is, a same PID identifier may be used in multiple network maps, while in each network map, this PID identifier points to a different set of addresses. For example, PID "mypid10" may be defined in "netmap1" and "netmap2" while in each network map, "mypid10" covers a different set of addresses.

Third, the EPS is only defined as a POST-mode service. Clients must request the properties for an explicit set of endpoint addresses. By contrast, [RFC7285] defines a GET-mode cost map resource which returns all available costs, so a client can get a full set of costs once, and then process cost lookups without querying the ALTO server. [RFC7285] does not define a similar service for endpoint properties. At first, a map of endpoint properties might seem impractical, because it could require enumerating the property value for every possible endpoint. However, in practice, it is highly unlikely that properties will be defined for every endpoint address. It is much more likely that properties may be defined for only a subset of endpoint addresses, and the specification of properties uses an aggregation representation to allow enumeration. This is particularly true if blocks of endpoint addresses with a common prefix (e.g., a CIDR) have the same value for a property. Entities in other domains may very well allow aggregated representation and hence be enumerable as well.

To address the three limitations, this document specifies a protocol extension for defining and retrieving ALTO properties:

- \* The first limitation is addressed by introducing a generic concept called ALTO Entity, which generalizes an endpoint and may represent a PID, a network element, a cell in a cellular network, an abstracted network element as defined in [I-D.ietf-alto-path-vector], or other physical or logical objects involved in a network topology. Each entity is included in a collection called an ALTO Entity Domain. Since each ALTO Entity Domain includes only one type of entities, each Entity Domain can be classified by the type of entities in it.
- \* The second limitation is addressed by using resource-specific entity domains. A resource-specific entity domain contains entities that are defined and identified with respect to a given ALTO information resource, which provides scoping. For example, an entity domain containing PIDs is identified with respect to the network map in which these PIDs are defined. Likewise, an entity domain containing local IP addresses may be defined with respect to a local network map.

- \* The third limitation is addressed by defining two new types of ALTO information resources: Property Map, detailed in [Section 7](#) and Filtered Property Map, detailed in [Section 8](#). The former is a GET-mode resource that returns the property values for all entities in one or more entity domains, and is analogous to a network map or a cost map in [\[RFC7285\]](#). The latter is a POST-mode resource that returns the values for sets of properties and entities requested by the client, and is analogous to a filtered network map or a filtered cost map.

The protocol extension defined in this document is augmentable. New entity domain types can be defined without revising the specification defined in this document. Similarly, new cost metrics and new endpoint properties can be defined in other documents without revising the protocol specification defined in [\[RFC7285\]](#).

### 1.1. Terminology

This document uses the following terms and abbreviations, that will be further defined in the document. While this document introduces the feature "entity property map", it will use both the term "property map" and "entity property map" to refer to this feature.

- \* Transaction: A request/response exchange between an ALTO client and an ALTO server.
- \* Client: When used with a capital "C", this term refers to an ALTO client. Note that expressions "ALTO client" and "ALTO Client" are equivalent.
- \* Server: When used with a capital "S", this term refers to an ALTO server. Note that expressions "ALTO server" and "ALTO Server" are equivalent.
- \* EPM: An abbreviation for entity property map.
- \* FPM: An abbreviation for filtered property map.
- \* EPS: An abbreviation for Endpoint Property Service.

## 2. Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [BCP 14](#) [\[RFC2119\]](#) [\[RFC8174\]](#) when, and only when, they appear in all capitals, as shown here. When the words appear in lower case, they are to be interpreted with their natural language meanings.

### 3. Basic Features of the Entity Property Map Extension

This section gives a high-level overview of the basic features involved in ALTO Entity Property Maps. It assumes the reader is familiar with the ALTO protocol [RFC7285]. The purpose of this extension is to allow conveying properties on objects that extend ALTO Endpoints and are called ALTO Entities, or entities for short.

The features introduced in this section can be used as standalone. However, in some cases, these features may depend on particular information resources and need to be defined with respect to them. To this end, [Section 4](#) introduces additional features that extend the ones presented in the present section.

The Entity Property Maps extension described in this document introduces a number of features that are summarized in [Appendix A](#), where Table 4 lists the features and references the sections in this document that give a high-level and normative description thereof.

#### 3.1. Entity

The concept of an ALTO Entity generalizes the concept of an ALTO Endpoint defined in [Section 2.1 of \[RFC7285\]](#). An entity is an object that can be an endpoint that is defined by its network address, but can also be an object that has a defined mapping to a set of one or more network addresses or an object that is not even related to any network address. Thus, whereas all endpoints are entities, not all entities are endpoints.

Examples of entities are:

- \* an ALTO endpoint, defined in [RFC7285], that represents an application or a host identified by a communication address (e.g., an IPv4 or IPv6 address) in a network,
- \* a PID, defined in [RFC7285], that has a provider defined human-readable identifier specified by an ALTO network map, which maps a PID to a set of IPv4 and IPv6 addresses,
- \* an autonomous system (AS), that has an AS number (ASN) as its identifier and maps to a set of IPv4 and IPv6 addresses,
- \* a country with a code as specified in [ISO3166-1], to which applications such as CDN providers associate properties and capabilities,

- \* a TCP/IP network flow, that is identified by a TCP/IP 5-Tuple specifying its source and destination addresses and port numbers and the utilized protocol,
- \* a routing element, that is specified in [\[RFC7921\]](#) and is associated with routing capabilities information,
- \* an abstract network element, that represents an abstraction of a network part such as a router, one or more links, a network domain or their aggregation.

### 3.2. Entity Domain

An entity domain defines a set of entities of the same semantic type. An entity domain is characterized by its type and identified by its name.

In this document, an entity is owned by exactly one entity domain name. An entity identifier points to exactly one entity. If two entities in two different entity domains refer to the same physical or logical object, they are treated as different entities. For example, if an end host has both an IPv4 and an IPv6 address, these two addresses will be treated as two entities, defined respectively in the "ipv4" and "ipv6" entity domains.

#### 3.2.1. Entity Domain Type

The type of an entity domain type defines the semantics of a type of entity. Entity domain types can be defined in different documents. For example: the present document defines entity domain types "ipv4", "ipv6" and "pid" in sections [Section 6.1](#) and [Section 6.2](#). The entity domain type "ane", that defines Abstract Network Elements (ANEs), is introduced in [\[I-D.ietf-alto-path-vector\]](#). The entity domain type that defines country codes is introduced in [\[I-D.ietf-alto-cdni-request-routing-alto\]](#). An entity domain type MUST be registered at the IANA, as specified in section [Section 12.2.2](#) and similarly to an ALTO address type.

### 3.2.2. Entity Domain Name

The name of an entity domain is defined in the scope of an ALTO server. An entity domain name can sometimes be identical to the name of its relevant entity domain type. This is the case when the entities of a domain have an identifier that points to the same object throughout all the information resources of the Server that provide entity properties for this domain. For example, a domain of type "ipv4" containing entities identified by a public IPv4 address can be named "ipv4" because its entities are uniquely identified by all the Server resources.

In some cases the name of an entity domain needs to be different from simply its entity domain type. Indeed, for some domain types, entities are defined relative to a given information resource. This is the case for entities of domain type "pid". A PID is defined relative to a network map. For example: an entity "mypid10" of domain type "pid" may be defined in a given network map and be undefined in other network maps. Or "mypid10" may even be defined in two different network maps and map, in each of these network maps, to a different set of endpoint addresses. In this case, naming an entity domain only by its type "pid" does not guarantee that its set of entities is owned by exactly one entity domain.

[Section 4.2](#) and [Section 5.1.2](#) of this document describe how a domain is uniquely identified, across the ALTO Server, by a name that associates the domain type and the related information resource.

### 3.3. Entity Property Type

An entity property defines a property of an entity. This is similar to the endpoint property defined in [Section 7.1 of \[RFC7285\]](#). An entity property can convey either network-aware or network-agnostic information. Similarly to an entity domain, an entity property is characterized by its type and identified by its name. An entity property type MUST be registered at the IANA, as specified in [section Section 12.3](#).

Below are some examples with real and fictitious entity domain and property names:

- \* an entity in the "ipv4" domain type may have a property whose value is an Autonomous System (AS) number indicating the AS that owns this IPv4 address and another property named "countrycode" indicating a country code mapping to this address,

- \* an entity identified by its country code in the entity domain type "countrycode", defined in [\[I-D.ietf-alto-cdni-request-routing-alto\]](#) may have a property indicating what delivery protocol is used by a CDN,
- \* an entity in the "netmap1.pid" domain may have a property that indicates the central geographical location of the endpoints it includes.

It should be noted that some identifiers may be used for both an entity domain type and a property type. For example:

- \* the identifier "countrycode" may point to both the entity domain type "countrycode" and the fictitious property type "countrycode".
- \* the identifier "pid" may point to both the entity domain type "pid" and the property type "pid".

Likewise, a same identifier may point to both a domain name and a property name. For example: the identifier "netmap10.pid" may point to either the domain defined by the PIDs of network map "netmap10" or to a property that returns, for an entity defined by its IPv4 address, the PID of netmap10 that contains this entity. Such cases will be further explained in [Section 4](#).

### 3.4. New information resource and media type: ALTO Property Map

This document introduces a new ALTO information resource named Property Map. An ALTO property map provides a set of properties on one or more sets of entities. A property may apply to different entity domain types and names. For example, an ALTO property map may define the "ASN" property for both "ipv4" and "ipv6" entity domains.

The present extension also introduces a new media type.

This document uses the same definition of an information resource as [Section 9.1 of \[RFC7285\]](#). ALTO uses media types to uniquely indicate the data format used to encode the content to be transmitted between an ALTO server and an ALTO client in the HTTP entity body. In the present case, an ALTO property map resource is defined by the media type "application/alto-propmap+json".

A Property Map can be queried as a GET-mode resource, thus conveying all properties on all entities indicated in its capabilities. It can also be queried as a POST-mode resource, thus conveying a selection of properties on a selection of entities.

#### 4. Advanced Features of the Entity Property Map Extension

This section gives a high-level overview of the advanced features involved in ALTO Entity Property Maps. Most of these features are defined to extend the ones defined in [Section 3](#).

##### 4.1. Entity Identifier and Entity Domain Name

In [\[RFC7285\]](#), an endpoint has an identifier that is explicitly associated with the "ipv4" or "ipv6" address domain. Examples are "ipv4:192.0.2.14" and "ipv6:2001:db8::12".

In this document, an entity must be owned by exactly one entity domain name and an entity identifier must point to exactly one entity. To ensure this, an entity identifier is explicitly attached to the name of its entity domain and an entity domain type characterizes the semantics and identifier format of its entities.

The encoding format of an entity identifier is further specified in [Section 5.1.3](#) of this document.

For instance:

- \* if an entity is an endpoint with example routable IPv4 address "192.0.2.14", its identifier is associated with domain name "ipv4" and is "ipv4:192.0.2.14",
- \* if an entity is a PID named "mypid10" in network map resource "netmap2", its identifier is associated with domain name "netmap2.pid" and is "netmap2.pid:mypid10".

##### 4.2. Resource-Specific Entity Domain Name

Some entities are defined and identified uniquely and globally. This is the case for instance when entities are endpoints that are identified by a routable IPv4 or IPv6 address. The entity domain for such entities can be globally defined and named "ipv4" or "ipv6". Those entity domains are called resource-agnostic entity domains in this document, as they are not associated with any specific ALTO information resources.

Some other entities and entity types are only defined relatively to a given information resource. This is the case for entities of domain type "pid", that can only be understood with respect to the network map where they are defined. For example, a PID named "mypid10" may be defined to represent a set S1 of IP addresses in a network map resource named "netmap1". Another network map "netmap2" may use the same name "mypid10" and define it to represent another set S2 of IP

addresses. The identifier "pid:mypid10" may thus point to different objects because the information on the originating information resource is lost.

To solve this ambiguity, the present extension introduces the concept of resources-specific entity domain. This concept applies to domain types where entities are defined relatively to a given information resource. It can also apply to entity domains that are defined locally, such as local networks of objects identified with a local IPv4 address.

In such cases, an entity domain type is explicitly associated with an identifier of the information resource where these entities are defined. Such an information resource is referred to as the "specific information resource". Using a resource-aware entity domain name, an ALTO property map can unambiguously identify distinct entity domains of the same type, on which entity properties may be queried. Examples of resource-specific entity domain names may look like: "netmap1.pid" or "netmap2.pid". Thus, a name association such as "netmap1.pid:mypid10" and "netmap2.pid:mypid10" allows to distinguish the two abovementioned PIDs that are both named "mypid10" but in two different resources, "netmap1" and "netmap2".

An information resource is defined in the scope of an ALTO Server and so is an entity domain name. The format of a resource-specific entity domain name is further specified in [Section 5.1.2](#).

#### 4.3. Resource-Specific Entity Property Value

Like entity domains, some types of properties are defined relatively to an information resource. That is, an entity may have a property of a given type, whose values are associated to different information resources.

For example, suppose entity "192.0.2.34" defined in the "ipv4" domain has a property of type "pid", whose value is the PID to which address "192.0.2.34" is attached in a network map. The mapping of network addresses to PIDs is specific to a network map and probably different from one network map resource to another one. Thus, if a property "pid" is defined for entity "192.0.2.34" in two different network maps "netmap1" and "netmap2", the value for this property will likely be a different value in "netmap1" and "netmap2".

To support information resource dependent property values, this document uses the same approach as in [Section 10.8.1 of \[RFC7285\]](#) entitled "Resource-Specific Endpoint Properties". When a property value depends on a given information resource, the name of this property MUST be explicitly associated with the information resource that defines it.

For example, the property "pid" queried on entity "ipv4:192.0.2.34" and defined in both "netmap1" and "netmap2", can be named "netmap1.pid" and "netmap2.pid". This allows a Client to get a property of the same type but defined in different information resources with a single query. Specifications on the property name format are provided in [Section 5.2](#).

#### 4.4. Entity Hierarchy and Property Inheritance

For some domain types, entities can be grouped in a set and be defined by the identifier of this set. This is the case for domain types "ipv4" and "ipv6", where individual Internet addresses can be grouped in blocks. When a same property value applies to a whole set, a Server can define a property for the identifier of this set instead of enumerating all the entities and their properties. This allows a substantial reduction of transmission payload both for the Server and the Client. For example, all the entities included in the set defined by the address block "ipv6:2001:db8::1/64" share the same properties and values defined for this block.

Additionally, entity sets sometimes are related by inclusion, hierarchy or other relations. This allows defining inheritance rules for entity properties that propagate properties among related entity sets. The Server and the Client can use these inheritance rules for further payload savings. Entity hierarchy and property inheritance rules are specified in the documents that define the applicable domain types. The present document defines these rules for the "ipv4" and "ipv6" domain types.

This document introduces, for applicable domain types, "Entity Property Inheritance rules", with the following concepts: Entity Hierarchy, Property Inheritance and Property Value Unicity. A detailed specification of entity hierarchy and property inheritance rules is provided in [Section 5.1.4](#).

#### 4.4.1. Entity Hierarchy

An entity domain may allow using a single identifier to identify a set of individual entities. For example, a CIDR block can be used to identify a set of IPv4 or IPv6 entities. A CIDR block is called a hierarchical entity identifier, as it can reflect inclusion relations among entity sets. That is, in an entity hierarchy, "supersets" are defined at upper levels and include "subsets" defined at lower levels." For example, the CIDR "ipv4:192.0.1.0/24" includes all the individual IPv4 entities identified by the CIDR "ipv4:192.0.1.0/26".

#### 4.4.2. Property Inheritance

A property may be defined for a hierarchical entity identifier, while it may be undefined for individual entities covered by this identifier. In this case, these individual entities inherit the property value defined for the identifier that covers them. For example, suppose a property map defines a property P for which it assigns value V1 only for the hierarchical entity identifier "ipv4:192.0.1.0/24" but not for individual entities in this block. Suppose also that inheritance rules are specified for CIDR blocks in the "ipv4" domain type. When receiving this property map, a Client can infer that entity "ipv4:192.0.1.1" inherits the property value V1 of block "ipv4:192.0.1.0/24" because the address "ipv4:192.0.1.1" is included in the CIDR block "ipv4:192.0.1.0/24".

Property value inheritance rules also apply among entity sets. A property map may define values for an entity set belonging to a hierarchy but not for "subsets" that are covered by this set identifier. In this case, inheritance rules must specify how entities in "subsets" inherit property values from their "superset". For instance, if a property P is defined only for the entity set identified by address block "ipv4:192.0.1.0/24", the entity set identified by "ipv4:192.0.1.0/30" and thus included in the former set, may inherit the property P value from set "ipv4:192.0.1.0/24".

#### 4.4.3. Property Value Unicity

The inheritance rules must ensure that an entity belonging to a hierarchical set of entities inherits no more than one property value, for the sake of consistency. Indeed, a property map may define a property on a hierarchy of entity sets that inherit property values from one or more supersets (located at upper levels). On the other hand, a property value, defined on a subset (located at a lower level) may be different from the value defined on a superset. In such a case, subsets may potentially end up with different property values. This may be the case for address blocs with increasing prefix length, on which a property value gets increasingly accurate

and thus may differ. For example, a fictitious property such as "geo-location" or "average transfer volume" may be defined at a progressively finer grain for lower level subsets of entities, defined with progressively longer CIDR prefixes. It seems more interesting to have property values of progressively higher accuracy. A unicity rule, applied to the entity domain type must specify an arbitration rule among the different property values for an entity. An example illustrating the need for such rules is provided in [Section 6.1.3](#).

#### 4.5. Supported Properties on Entity Domains in Property Map Capabilities

A property type is not necessarily applicable to any domain type, or an ALTO Server may choose not to provide a property on all applicable domains. For instance, a property type reflecting link bandwidth is likely not defined on entities of a domain of type "country-code". Therefore an ALTO server providing Property Maps needs to specify the properties that can be queried on the different entity domains it supports.

This document explains how the Information Resources Directory (IRD) capabilities of a Property Map resource unambiguously expose what properties a Client can query on a given entity domain.

- \* a field named "mappings" lists the names of the entity domains supported by the Property Map,
- \* for each listed entity domain, a list of the names of the applicable properties is provided.

An example is provided in [Section 10.3](#). The "mappings" field associates entity domains and properties that can be resource-agnostic or resource-specific. This allows a Client to formulate compact and unambiguous entity property queries, possibly relating to one or more information resources. In particular:

- \* it avoids a Client to query a property on entity domains on which it is not defined,
- \* it allows a Client to query, for an entity E, values for a property P that are defined in several information resources,
- \* it allows a Client to query a property P on entities that are defined in several information resources.

Further specifications are provided in [Section 7.4](#).

#### 4.6. Defining Information Resource for Resource-Specific Entity Domains

A Client willing to query properties on entities belonging to a domain needs to know how to retrieve these entities. To this end, the Client can look up the "mappings" field exposed in IRD capabilities of a property map, see [Section 4.5](#). This field, in its keys, exposes all the entity domains supported by the property map. The syntax of the entity domain identifier specified in [Section 5.1.2](#) allows the client to infer whether the entity domain is resource-specific or not. The Client can extract, if applicable, the identifier of the specific resource, query the resource and retrieve the entities. For example:

- \* an entity domain named "netmap1.ipv4" includes the IPv4 addresses that appear in the "ipv4" field of the endpoint address group of each PID in the network map "netmap1", and that cannot be recognized outside "netmap1" because, for instance, these are local non-routable addresses,
- \* an entity domain named "netmap1.pid" includes the PIDs listed in network map "netmap1".
- \* an entity domain named "ipv4" is resource-agnostic and covers all the routable IPv4 addresses.

Besides, it is also necessary to inform a Client about which associations of specific resources and entity domain types are allowed, because it is not possible to prevent a Server from exposing inappropriate associations. An informed Client will just ignore inappropriate associations exposed by a Server and avoid error-prone transactions with the Server.

For example, the association "costmap3.pid" is not allowed for the following reason: although a cost map exposes PID identifiers, it does not define the set of addresses included in this PID. Neither does a cost map list all the PIDs on which properties can be queried, because a cost map only exposes PID pairs on which a queried cost type is defined. Therefore, the resource "costmap3" does not enable a Client to extract information on the existing PID entities or on the addresses they contain.

Instead, the cost map uses a network map, where all the PIDs used in a cost map are defined together with the addresses contained by the PIDs. This network map is qualified in this document as the Defining Information Resource for the entity domain of type "pid" and this concept is explained in [Section 4.6.1](#).

#### 4.6.1. Defining Information Resource and its Media Type

For the reasons explained in the previous section, this document introduces the concept of "Defining Information Resource and its Media Type".

A defining information resource for an entity domain D is the information resource where entities of D are defined. That is, all the information on the entities of D can be retrieved in this resource. This concept applies to resource-specific entity domains. This is useful for entity domain types that are by essence domain-specific, such as "pid" and "ane" domain types. It is also useful for resource-specific entity domains constructed from resource-agnostic domain types, such as network map specific domains of local IPv4 addresses.

The defining information resource of a resource-specific entity domain D is unique and has the following specificities:

- \* it has an entry in the IRD,
- \* it defines the entities of D,
- \* it does not use another information resource that defines these entities,
- \* it defines and exposes entity identifiers that are all persistent.
- \* its media type is unique and equal to the one that is specified for the defining information resource of an entity domain type.

A fundamental attribute of a defining information resource is its media type. There is a unique association between an entity domain type and the media type of its defining information resource. When an entity domain type allows associations with defining information resources, the media type of the potential defining information resource MUST be specified:

- \* in the document that defines this entity domain type,
- \* in the IANA ALTO Entity Domain Type Registry and related information.

When the Client wants to use a resource-specific entity domain, it needs to be cognizant of the media-type of its defining information resource. If the Server exposes a resource-specific entity domain with a non-compliant media type for the defining resource, the Client MUST ignore the entities from that entity domain to avoid errors.

#### 4.6.2. Examples of Defining Information Resources and Their Media Types

Here are examples of defining information resource types and their media types associated to different entity domain types.

- \* For entity domain type "pid": the media type of the specific resource is "application/alto-networkmap+json", because PIDs are defined in network map resources.
- \* For entity domain types "ipv4" and "ipv6": the media type of the specific resource is "application/alto-networkmap+json", because IPv4 and IPv6 addresses covered by the Server are defined in network map resources.
- \* For entities of domain type "ane": [[I-D.ietf-alto-path-vector](#)] defines entities named "ANE", where ANE stands for Abstracted Network Element, and the entity domain type "ane". An ANE may have a persistent identifier, say, "entity-4", that is provided by the Server as a value of the "persistent-entity-id" property of this ANE. Further properties may then be queried on an ANE by using its persistent entity ID. These properties are available from a persistent property map, that defines properties on a specific "ane" domain. Together with the persistent identifier, the Server also provides the property map resource identifier where the "ane" domain containing "entity-4" is defined. The definition of the "ane" entity domain containing "entity-4" is thus specific to the property map. Therefore, for entities of domain type "ane" that have a persistent identifier, the media type of the specific information resource is "application/alto-propmap+json".
- \* Last, the entity domain types "asn" and "countrycode" defined in [[I-D.ietf-alto-cdni-request-routing-alto](#)] do not have a defining information resource. Indeed, the entity identifiers in these two entity domain types are already standardized in documents that the Client can use.

#### 4.7. Defining Information Resource for Resource-Specific Property Values

As explained in [Section 4.3](#), a property type may take values that are resource-specific. This is the case for property type "pid", whose values are by essence defined relatively to a specific network map. That is, the PID value returned for an IPv4 address is specific to the network map defining this PID and may differ from one network map to another one.

Another example is provided in [I-D.ietf-alto-cdni-request-routing-alto] that defines property type "cdni-capabilities". The value of this property is specific to a CDNI Advertisement resource, that provides a list of CDNI capabilities. The property is provided for entity domain types "ipv4", "ipv6", "asn" and "countrycode". A CDNI Advertisement resource does however not define PID values for IPv4 addresses while a network map does not define CDNI capabilities for IPv4 addresses.

Similarly to resource-specific entity domains, the Client needs to be cognizant of appropriate associations of information resource and property types. Therefore, when specifying and registering a property type whose values are resource-specific, the media type of its defining information resource needs to be specified. For example:

- \* The media type of the defining information resource for property type "pid" is "application/alto-networkmap+json".
- \* The media type of the defining information resource for property type "cdni-capabilities" defined in [I-D.ietf-alto-cdni-request-routing-alto] is "application/alto-cdni+json".

## 5. Protocol Specification: Basic Data Types

### 5.1. Entity Domain

#### 5.1.1. Entity Domain Type

An entity domain has a type, which is uniquely identified by a string that MUST be no more than 64 characters, and MUST NOT contain characters other than US-ASCII alphanumeric characters (U+0030-U+0039, U+0041-U+005A, and U+0061-U+007A), the hyphen ('-', U+002D), or the low line ('\_', U+005F).

For example, the strings "ipv4", "ipv6", and "pid" are valid entity domain types. "ipv4.anycast" and "pid.local" are invalid.

The type EntityDomainType is used in this document to denote a JSON string meeting the preceding requirements.

An entity domain type defines the semantics of a type of entity, independently of any specifying resource. Each entity domain type MUST be registered with the IANA, following the procedure specified in [Section 12.2.2](#) of this document. The format of the entity identifiers (see [Section 5.1.3](#)) in that type of entity domain, as well as any hierarchical or inheritance rules (see [Section 5.1.4](#)) for those entities, MUST be specified at the same time.

#### 5.1.2. Entity Domain Name

As said in [Section 3.2](#) when introducing entity domains, an entity domain is characterized by its type and identified by its name.

This document distinguishes three categories of entity domains: resource-specific entity domains, resource-agnostic entity domains and self-defined entity domains. Their entity domain names are constructed as specified in the following sub-sections.

Each entity domain is identified by a unique entity domain name which is a string of the following format:

EntityDomainName ::= [ [ ResourceID ] '.' ] EntityDomainType

Where the presence and construction of component:

"[ [ ResourceID ] '.' ]"

depends on the category of entity domain.

Note that the '.' separator is not allowed in EntityDomainType and hence there is no ambiguity on whether an entity domain name refers to a resource-agnostic entity domain or a resource-specific entity domain.

Note also that [Section 10.1 of \[RFC7285\]](#) specifies the format of the PID Name which is the format of the resource ID including the following specification: "the '.' separator is reserved for future use and MUST NOT be used unless specifically indicated in this document, or an extension document". The present extension keeps the format specification of [\[RFC7285\]](#), hence the '.' separator MUST NOT be used in an information resource ID.

#### 5.1.2.1. Resource-specific Entity Domain

A resource-specific entity domain is identified by an entity domain name constructed as follows. It MUST start with a resource ID using the ResourceID type defined in [Section 10.2 of \[RFC7285\]](#), followed by the '.' separator (U+002E), followed by a string of the type EntityDomainType specified in [Section 5.1.1](#).

For example, if an ALTO server provides two network maps "netmap-1" and "netmap-2", these network maps can define two resource-specific domains of type "pid", respectively identified by "netmap-1.pid" and "netmap-2.pid".

#### 5.1.2.2. Resource-agnostic Entity Domain

A resource-agnostic entity domain contains entities that are identified independently of any information resource. Hence, the identifier of a resource-agnostic entity domain is simply the identifier of its entity domain type. For example, "ipv4" and "ipv6" identify the two resource-agnostic Internet address entity domains defined in [Section 6.1](#).

#### 5.1.2.3. Self-defined Entity Domain

A property map can define properties on entities that are specific to a unique information resource, which is the property map itself. This may be the case when an ALTO Server provides properties on a set of entities that are defined only in this property map, are not relevant to another one and do not depend on another specific resource.

For example: a specialised property map may define a domain of type "ane", defined in [\[I-D.ietf-alto-path-vector\]](#), that contains a set of ANEs representing data centers, that each have a persistent identifier and are relevant only to this property map.

In this case, the entity domain is qualified as "self-defined". The identifier of a self-defined entity domain can be of the format:

EntityDomainName ::= '.' EntityDomainType

where '.' indicates that the entity domain only exists within the property map resource using it.

A self-defined entity domain can be viewed as a particular case of resource-specific entity domain, where the specific resource is the current resource that uses this entity domain. In that case, for the sake of simplification, the component "ResourceID" SHOULD be omitted in its entity domain name.

#### 5.1.3. Entity Identifier

Entities in an entity domain are identified by entity identifiers (EntityID) of the following format:

EntityID ::= EntityDomainName ':' DomainTypeSpecificEntityID

Examples from the Internet address entity domains include individual IP addresses such as "net1.ipv4:192.0.2.14" and "net1.ipv6:2001:db8::12", as well as address blocks such as "net1.ipv4:192.0.2.0/26" and "net1.ipv6:2001:db8::1/48".

The format of the second part of an entity identifier depends on the entity domain type, and MUST be specified when defining a new entity domain type and registering it with the IANA. Identifiers MAY be hierarchical, and properties MAY be inherited based on that hierarchy. The rules defining any hierarchy or inheritance MUST be defined when the entity domain type is registered.

The type EntityID is used in this document to denote a JSON string representing an entity identifier in this format.

Note that two entity identifiers with different valid textual representations may refer to the same entity, for a given entity domain. For example, the strings "net1.ipv6:2001:db8::1" and "net1.ipv6:2001:db8:0:0:0:0:1" refer to the same entity in the "ipv6" entity domain. Such equivalences should be established by the object represented by DomainTypeSpecificEntityID, for example, [RFC5952] establishes equivalence for IPv6 addresses, while [RFC4632] does so for IPv4 addresses.

#### 5.1.4. Hierarchy and Inheritance

To simplify the representation, some types of entity domains allow the ALTO Client and Server to use a hierarchical entity identifier format to represent a block of individual entities. For instance, in an IPv4 domain "net1.ipv4", a CIDR "net1.ipv4:192.0.2.0/26" covers 64 individual IPv4 entities. In this case, the corresponding property inheritance rule MUST be defined for the entity domain type. The hierarchy and inheritance rule MUST have no ambiguity.

## 5.2. Entity Property

Each entity property has a type to indicate the encoding and the semantics of the value of this entity property, and has a name to identify it.

### 5.2.1. Entity Property Type

The type `EntityPropertyType` is used in this document to indicate a string denoting an entity property type. The string **MUST** be no more than 32 characters, and it **MUST NOT** contain characters other than US-ASCII alphanumeric characters (U+0030-U+0039, U+0041-U+005A, and U+0061-U+007A), the hyphen ('-', U+002D), the colon(':', U+003A), or the low line ('\_', U+005F). Note that the '.' separator is not allowed because it is reserved to separate an entity property type and an information resource identifier when an entity property is resource-specific.

Each entity property type **MUST** be registered with the IANA, following the procedure specified in [Section 12.3](#) of this document. The intended semantics of the entity property type **MUST** be specified at the same time.

Identifiers prefixed with "priv:" are reserved for Private Use [[RFC8126](#)] without a need to register with IANA. All other identifiers for entity property types appearing in an HTTP request or response with an "application/alto-\*" media type **MUST** be registered in the "ALTO Entity Property Type Registry", defined in [Section 12.3](#). For an entity property identifier with the "priv:" prefix, an additional string (e.g., company identifier or random string) **MUST** follow the prefix to reduce potential collisions, that is, the string "priv:" alone is not a valid endpoint property identifier.

To distinguish from the endpoint property type, the entity property type has the following characteristics:

- \* Some entity property types are applicable to entities in particular entity domain types only. For example, the property type "pid" is applicable to entities in the entity domain types "ipv4" or "ipv6" while is not applicable to entities in an entity domain of type "pid".
- \* The intended semantics of the value of an entity property may also depend on the entity domain type. For example, suppose that a property named "geo-location" is defined as the coordinates of a point, encoded as: "latitude longitude [altitude]." When applied to an entity that represents a specific host computer, identified by an address in an entity domain of type "ipv4" or "ipv6", the

"geo-location" property would define the host's location. However, when applied to an entity in a "pid" domain type, the property would indicate the location of the center of all hosts in this "pid" entity.

#### 5.2.2. Entity Property Name

Each entity property is identified by an entity property name, which is a string of the following format:

```
EntityPropertyName ::= [ ResourceID ] '.' EntityPropertyType
```

Similar to the endpoint property type defined in [Section 10.8 of \[RFC7285\]](#), each entity property may be defined by either the property map itself (self-defined) or some other specific information resource (resource-specific).

The entity property name of a resource-specific entity property starts with a string of the type ResourceID defined in [\[RFC7285\]](#), followed by the '.' separator (U+002E) and a EntityDomainType typed string. For example, the "pid" properties of an "ipv4" entity defined by two different maps "net-map-1" and "net-map-2" are identified by "net-map-1.pid" and "net-map-2.pid" respectively.

The specific information resource of an entity property may be the current information resource itself, that is, the property map defining the property. In that case, the ResourceID in the property name SHOULD be ignored. For example, the property name ".asn" applied to an entity identified by its IPv4 address, indicates the AS number of the AS that "owns" the entity, where the returned AS number is defined by the property map itself.

#### 5.2.3. Format for Entity Property Value

[\[RFC7285\]](#) in [Section 11.4.1.6](#), specifies that an implementation of the Endpoint Property Service specified in [\[RFC7285\]](#) SHOULD assume that the property value is a JSONString and fail to parse if it is not. This document extends the format of a property value by allowing it to be a JSONValue instead of just a JSONString.

### 6. Entity Domain Types Defined in this Document

This document requires the definition of each entity domain type MUST include (1) the entity domain type name and (2) domain-specific entity identifiers, and MAY include (3) hierarchy and inheritance semantics optionally. This document defines three initial entity domain types as follows.

## 6.1. Internet Address Domain Types

The document defines two entity domain types (IPv4 and IPv6) for Internet addresses. Both types are resource-agnostic entity domain types and hence define corresponding resource-agnostic entity domains as well. Since the two domains use the same hierarchy and inheritance semantics, we define the semantics together, instead of repeating for each.

### 6.1.1. Entity Domain Type: IPv4

#### 6.1.1.1. Entity Domain Type Identifier

ipv4

#### 6.1.1.2. Domain-Specific Entity Identifiers

Individual addresses are strings as specified by the IPv4Addresses rule of [Section 3.2.2 of \[RFC3986\]](#); Hierarchical addresses are prefix-match strings as specified in [Section 3.1 of \[RFC4632\]](#). To define properties, an individual Internet address and the corresponding full-length prefix are considered aliases for the same entity. An individual Internet address and the corresponding full-length prefix are considered aliases for the same entity on which to define properties. Thus, "ipv4:192.0.2.0" and "ipv4:192.0.2.0/32" are equivalent.

### 6.1.2. Entity Domain Type: IPv6

#### 6.1.2.1. Entity Domain Type Identifier

ipv6

#### 6.1.2.2. Domain-Specific Entity Identifiers

Individual addresses are strings as specified by [Section 4 of \[RFC5952\]](#); Hierarchical addresses are prefix-match strings as specified in [Section 7 of \[RFC5952\]](#). To define properties, an individual Internet address and the corresponding 128-bit prefix are considered aliases for the same entity. That is, "ipv6:2001:db8::1" and "ipv6:2001:db8::1/128" are equivalent, and have the same set of properties.

### 6.1.3. Hierarchy and Inheritance of Internet Address Domains

Both Internet address domains allow property values to be inherited. Specifically, if a property P is not defined for a specific Internet address I, but P is defined for a hierarchical Internet address C which prefix-matches I, then the address I inherits the value of P defined for the hierarchical address C. If more than one such hierarchical addresses define a value for P, I inherits the value of P in the hierarchical address with the longest prefix. Note that this longest prefix rule ensures no multiple value inheritances, and hence no ambiguity.

Hierarchical addresses can also inherit properties: if a property P is not defined for the hierarchical address C, but is defined for another hierarchical address C' which covers all IP addresses in C, and C' has a shorter prefix length than C, then C MAY inherit the property from C'. If there are multiple such hierarchical addresses like C', C MUST inherit from the hierarchical address having the longest prefix length.

As an example, suppose that a server defines a property P for the following entities:

```
ipv4:192.0.2.0/26: P=v1
ipv4:192.0.2.0/28: P=v2
ipv4:192.0.2.0/30: P=v3
ipv4:192.0.2.0:   P=v4
```

Figure 1: Defined Property Values.

Then the following entities have the indicated values:

```
ipv4:192.0.2.0:   P=v4
ipv4:192.0.2.1:   P=v3
ipv4:192.0.2.16:  P=v1
ipv4:192.0.2.32:  P=v1
ipv4:192.0.2.64:  (not defined)
ipv4:192.0.2.0/32: P=v4
ipv4:192.0.2.0/31: P=v3
ipv4:192.0.2.0/29: P=v2
ipv4:192.0.2.0/27: P=v1
ipv4:192.0.2.0/25: (not defined)
```

Figure 2: Inherited Property Values.

An ALTO server MAY explicitly indicate a property as not having a value for a particular entity. That is, a server MAY say that property P of entity X is "defined to have no value", instead of "undefined". To indicate "no value", a server MAY perform different behaviours:

- \* If that entity would inherit a value for that property, then the ALTO server MUST return a "null" value for that property. In this case, the ALTO client MUST recognize a "null" value as "no value" and "do not apply the inheritance rules for this property."
- \* If the entity would not inherit a value, then the ALTO server MAY return "null" or just omit the property. In this case, the ALTO client cannot infer the value for this property of this entity from the Inheritance rules. So the client MUST interpret that this property has no value.

If the ALTO server does not define any properties for an entity, then the server MAY omit that entity from the response.

#### 6.1.4. Defining Information Resource Media Type for domain types IPv4 and IPv6

Entity domain types "ipv4" and "ipv6" both allow to define resource specific entity domains. When resource specific domains are defined with entities of domain type "ipv4" or "ipv6", the defining information resource for an entity domain of type "ipv4" or "ipv6" MUST be a Network Map. The media type of a defining information resource is therefore:

application/alto-networkmap+json

#### 6.2. Entity Domain Type: PID

The PID domain associates property values with the PIDs in a network map. Accordingly, this entity domain always depends on a network map.

##### 6.2.1. Entity Domain Type Identifier

pid

##### 6.2.2. Domain-Specific Entity Identifiers

The entity identifiers are the PID names of the associated network map.

### 6.2.3. Hierarchy and Inheritance

There is no hierarchy or inheritance for properties associated with PIDs.

### 6.2.4. Defining Information Resource Media Type for Domain Type PID

The entity domain type "pid" allows to define resource specific entity domains. When resource specific domains are defined with entities of domain type "pid", the defining information resource for entity domain type "pid" MUST be a Network Map. The media type of a defining information resource is therefore:

application/alto-networkmap+json

### 6.2.5. Relationship To Internet Addresses Domains

The PID domain and the Internet address domains are completely independent; the properties associated with a PID have no relation to the properties associated with the prefixes or endpoint addresses in that PID. An ALTO server MAY choose to assign all the properties of a PID to the prefixes in that PID or only some of these properties.

For example, suppose "PID1" consists of the prefix "ipv4:192.0.2.0/24", and has the property "P" with value "v1". The Internet address entities "ipv4:192.0.2.0" and "ipv4:192.0.2.0/24" in the IPv4 domain MAY have a value for the property "P", and if they do, it is not necessarily "v1".

## 6.3. Internet Address Properties vs. PID Properties

Because the Internet address and PID domains relate to completely distinct domain types, the question may arise as to which entity domain type is the best for a property. In general, the Internet address domain types are RECOMMENDED for properties that are closely related to the Internet address, or are associated with, and inherited through, hierarchical addresses.

The PID domain type is RECOMMENDED for properties that arise from the definition of the PID, rather than from the Internet address prefixes in that PID.

For example, because Internet addresses are allocated to service providers by blocks of prefixes, an "ISP" property would be best associated with Internet address domain types. On the other hand, a property that explains why a PID was formed, or how it relates to a provider's network, would best be associated with the PID domain type.

## 7. Property Map

A property map returns the properties defined for all entities in one or more domains, e.g., the "location" property of entities in "pid" domain, and the "ASN" property of entities in "ipv4" and "ipv6" domains.

[Section 10.4](#) gives an example of a property map request and its response.

### 7.1. Media Type

The media type of a property map is "application/alto-propmap+json".

### 7.2. HTTP Method

The property map is requested using the HTTP GET method.

### 7.3. Accept Input Parameters

None.

### 7.4. Capabilities

The capabilities are defined by an object of type `PropertyMapCapabilities`:

```
object {  
  EntityPropertyMapping mappings;  
} PropertyMapCapabilities;  
  
object-map {  
  EntityDomainName -> EntityPropertyName<1..*>;  
} EntityPropertyMapping
```

with fields:

`mappings`: A JSON object whose keys are names of entity domains and values are the supported entity properties of the corresponding entity domains.

### 7.5. Uses

The "uses" field of a property map resource in an IRD entry specifies dependent resources of this property map. It is an array of the resource ID(s) of the resource(s).

## 7.6. Response

If the entity domains in this property map depend on other resources, the "dependent-vtags" field in the "meta" field of the response MUST be an array that includes the version tags of those resources, and the order MUST be consistent with the "uses" field of this property map resource. The data component of a property map response is named "property-map", which is a JSON object of type `PropertyMapData`, where:

```
object {
  PropertyMapData property-map;
} InfoResourceProperties : ResponseEntityBase;

object-map {
  EntityID -> EntityProps;
} PropertyMapData;

object {
  EntityPropertyName -> JSONValue;
} EntityProps;
```

The `ResponseEntityBase` type is defined in [Section 8.4 of \[RFC7285\]](#).

Specifically, a `PropertyMapData` object has one member for each entity in the property map. The entity's properties are encoded in the corresponding `EntityProps` object. `EntityProps` encodes one name/value pair for each property, where the property names are encoded as strings of type `PropertyName`. A protocol implementation SHOULD assume that the property value is either a `JSONString` or a `JSON` "null" value, and fail to parse if it is not, unless the implementation is using an extension to this document that indicates when and how property values of other data types are signaled.

For each entity in the property map:

- \* If the entity is in a resource-specific entity domain, the ALTO server SHOULD only return self-defined properties and resource-specific properties which depend on the same resource as the entity does. The ALTO client SHOULD ignore the resource-specific property in this entity if their mapping is not registered in the ALTO Resource Entity Property Transfer Registry of the type of the corresponding resource.
- \* If the entity is in a shared entity domain, the ALTO server SHOULD return self-defined properties and all resource-specific properties defined for all resource-specific entities which have the same domain-specific entity identifier as this entity does.

For efficiency, the ALTO server SHOULD omit property values that are inherited rather than explicitly defined; if a client needs inherited values, the client SHOULD use the entity domain's inheritance rules to deduce those values.

## 8. Filtered Property Map

A filtered property map returns the values of a set of properties for a set of entities selected by the client.

[Section 10.5](#), [Section 10.6](#), [Section 10.7](#) and [Section 10.8](#) give examples of filtered property map requests and responses.

### 8.1. Media Type

The media type of a property map resource is "application/alto-propmap+json".

### 8.2. HTTP Method

The filtered property map is requested using the HTTP POST method.

### 8.3. Accept Input Parameters

The input parameters for a filtered property map request are supplied in the entity body of the POST request. This document specifies the input parameters with a data format indicated by the media type "application/alto-propmapparams+json", which is a JSON object of type `ReqFilteredPropertyMap`:

```
object {
  EntityID          entities<1..*>;
  EntityPropertyName properties<1..*>;
} ReqFilteredPropertyMap;
```

with fields:

**entities:** List of entity identifiers for which the specified properties are to be returned. The ALTO server MUST interpret entries appearing multiple times as if they appeared only once. The domain of each entity MUST be included in the list of entity domains in this resource's "capabilities" field (see [Section 8.4](#)).

**properties:** List of properties to be returned for each entity. Each

specified property MUST be included in the list of properties in this resource's "capabilities" field (see [Section 8.4](#)). The ALTO server MUST interpret entries appearing multiple times as if they appeared only once. Note that the "entities" and "properties" fields MUST have at least one entry each.

#### 8.4. Capabilities

The capabilities are defined by an object of type `PropertyMapCapabilities`, as defined in [Section 7.4](#).

#### 8.5. Uses

Same to the "uses" field of the Property Map resource (see [Section 7.5](#)).

#### 8.6. Filtered Property Map Response

The response MUST indicate an error, using ALTO protocol error handling, as defined in [Section 8.5 of \[RFC7285\]](#), if the request is invalid.

Specifically, a filtered property map request can be invalid in the following cases:

- \* An entity identifier in the "entities" field of the request is invalid if:
  - The domain of this entity is not defined in the "entity-domains" capability of this resource in the IRD,
  - The entity identifier is not valid for the entity domain.

A valid entity identifier does never generate an error, even if the filtered property map resource does not define any properties for it.

If an entity identifier in the "entities" field of the request is invalid, the ALTO server MUST return an "E\_INVALID\_FIELD\_VALUE" error defined in [Section 8.5.2 of \[RFC7285\]](#), and the "value" field of the error message SHOULD indicate the provided invalid entity identifier.

- \* A property name in the "properties" field of the request is invalid if this property name is not defined in the "properties" capability of this resource in the IRD.

When a filtered property map resource does not define a value for a property requested on a particular entity, it is not an error. In this case, the ALTO server MUST omit that property from the response for that endpoint.

If a property name in "properties" in the request is invalid, the ALTO server MUST return an "E\_INVALID\_FIELD\_VALUE" error defined in [Section 8.5.2 of \[RFC7285\]](#). The "value" field of the error message SHOULD indicate the property name.

The response to a valid request is the same as for the Property Map (see [Section 7.6](#)), except that:

- \* If the requested entities include entities in the shared entity domain, the "dependent-vtags" field in its "meta" field MUST include version tags of all dependent resources appearing in the "uses" field.
- \* If the requested entities only include entities in resource-specific entity domains, the "dependent-vtags" field in its "meta" field MUST include the version tags of the resources on which the requested resource-specific entity domains and the requested resource-specific properties are dependent on.
- \* The response only includes the entities and properties requested by the client. If an entity in the request is identified by a hierarchical identifier (e.g., a "ipv4" or "ipv6" prefix), the response MUST cover properties for all identifiers in this hierarchical identifier.

The filtered property map response MUST include all the inherited property values for the requested entities and all the entities which are able to inherit property values from the requested entities. To achieve this goal, the ALTO server MAY follow three rules:

- \* If a property for a requested entity is inherited from another entity not included in the request, the response SHOULD include this property for the requested entity. For example, A full property map may skip a property P for an entity A (e.g., ipv4:192.0.2.0/31) if P can be derived using inheritance from another entity B (e.g., ipv4:192.0.2.0/30). A filtered property map request may include only A but not B. In such a case, the property P SHOULD be included in the response for A.
- \* If there are entities covered by a requested entity but having different values for the requested properties, the response SHOULD include all those entities and the different property values for them. For example, considering a request for property P of entity

A (e.g., ipv4:192.0.2.0/31), if P has value v1 for A1=ipv4:192.0.2.0/32 and v2 for A2=ipv4:192.0.2.1/32, then, the response SHOULD include A1 and A2.

- \* If an entity identifier in the response is already covered by other entities identifiers in the same response, it SHOULD be removed from the response, for the sake of compactness. In the previous example, the entity A = ipv4:192.0.2.0/31 SHOULD be removed because A1 and A2 cover all the addresses in A.

An ALTO client should be aware that the entities in the response MAY be different from the entities in its request.

### 8.7. Entity property type defined in this document

This document defines the entity property type "pid". This property type extends the ALTO Endpoint Property Type "pid" defined in [section 7.1.1 of \[RFC7285\]](#) as follows: the property has the same semantics and applies to IPv4 and IPv6 addresses; the difference is that the IPv4 and IPv6 addresses have evolved from the status of endpoints to the status of entities.

The defining information resource for property type MUST be a network map. This document requests a IANA registration for this property

#### 8.7.1. Entity Property Type: pid

1. Identifier: pid
2. Semantics: the intended semantics are the same as in [\[RFC7285\]](#) for the ALTO Endpoint Property Type "pid"
3. Media type of defining information resource: application/alto-networkmap+json
4. Security considerations: for entity property type "pid" are the same as documented in [\[RFC7285\]](#) for the ALTO Endpoint Property Type "pid".

### 9. Impact on Legacy ALTO Servers and ALTO Clients

### 9.1. Impact on Endpoint Property Service

Since the Property Map and the Filtered Property Map defined in this document provide a functionality that covers the Endpoint Property Service (EPS) defined in [Section 11.4 of \[RFC7285\]](#), ALTO servers may prefer to provide Property Map and Filtered Property Map in place of EPS. However, for the legacy endpoint properties, it is recommended that ALTO servers also provide EPS so that legacy clients can still be supported.

### 9.2. Impact on Resource-Specific Properties

[Section 10.8 of \[RFC7285\]](#) defines two categories of endpoint properties: "resource-specific" and "global". Resource-specific property names are prefixed with the ID of the resource they depend on, while global property names have no such prefix. The property map and the filtered property map defined in this document define similar categories of entity properties. The difference is that entity property maps do not define "global" entity properties. Instead, they define "self-defined" entity properties as a special case of "resource-specific" entity properties, where the specific resource is the property map itself. This means that "self-defined" properties are defined within the scope of the property map.

### 9.3. Impact on Other Properties

In the present extension, properties can now be defined on sets of entity addresses, rather than just individual endpoint addresses as is the case in [RFC7285](#). This might change the semantics of a property. These sets can be for example hierarchical IP address blocks. For instance, a property such as fictitious "geo-location", defined on a set of IP addresses would have a value corresponding to the barycenter of this set of addresses.

## 10. Examples

### 10.1. Network Map

The examples in this section use a very simple default network map:

```
defaultpid:  ipv4:0.0.0.0/0  ipv6:::0/0
pid1:        ipv4:192.0.2.0/25
pid2:        ipv4:192.0.2.0/27
pid3:        ipv4:192.0.3.0/28
pid4:        ipv4:192.0.3.16/28
```

Figure 3: Example Default Network Map

And another simple alternative network map:

```
defaultpid:  ipv4:0.0.0.0/0  ipv6:::0/0
pid1:        ipv4:192.0.2.0/27
pid2:        ipv4:192.0.3.0/27
```

Figure 4: Example Alternative Network Map

## 10.2. Property Definitions

Beyond "pid", the examples in this section use four additional properties for Internet address domains, "ISP", "ASN", "country" and "state", with the following values:

	ISP	ASN	country	state
ipv4:192.0.2.0/23:	BitsRus	-	us	-
ipv4:192.0.2.0/28:	-	12345	-	NJ
ipv4:192.0.2.16/28:	-	12345	-	CT
ipv4:192.0.2.1:	-	-	-	PA
ipv4:192.0.3.0/28:	-	12346	-	TX
ipv4:192.0.3.16/28:	-	12346	-	MN

Figure 5: Example Property Values for Internet Address Domains

And the examples in this section use the property "region" for the PID domain of the default network map with the following values:

	region
pid:defaultpid:	-
pid:pid1:	us-west
pid:pid2:	us-east
pid:pid3:	us-south
pid:pid4:	us-north

Figure 6: Example Property Values for Default Network Map's PID Domain

Note that "-" means the value of the property for the entity is "undefined". So the entity would inherit a value for this property by the inheritance rule if possible. For example, the value of the "ISP" property for "ipv4:192.0.2.1" is "BitsRus" because of "ipv4:192.0.2.0/24". But the "region" property for "pid:defaultpid" has no value because no entity from which it can inherit.

Similar to the PID domain of the default network map, the examples in this section use the property "ASN" for the PID domain of the alternative network map with the following values:

	ASN
pid:defaultpid:	-
pid:pid1:	12345
pid:pid2:	12346

Figure 7: Example Property Values for Alternative Network Map's  
PID Domain

### 10.3. Information Resource Directory (IRD)

The following IRD defines ALTO Server information resources that are relevant to the Entity Property Service. It provides two property maps: one for the "ISP" and "ASN" properties, and another one for the "country" and "state" properties. The server could have provided a single property map for all four properties, but does not, presumably because the organization that runs the ALTO server believes that a client is not necessarily interested in getting all four properties.

The server provides several filtered property maps. The first returns all four properties, and the second returns only the "pid" property for the default network map.

The filtered property maps for the "ISP", "ASN", "country" and "state" properties do not depend on the default network map (it does not have a "uses" capability), because the definitions of those properties do not depend on the default network map. The Filtered Property Map providing the "pid" property does have a "uses" capability for the default network map, because the default network map defines the values of the "pid" property.

Note that for legacy clients, the ALTO server provides an Endpoint Property Service for the "pid" property defined on the endpoints of the default network map.

The server provides another filtered Property map resource, named "ane-dc-property-map", that returns a fictitious properties named "storage-capacity", "ram" and "cpu" for ANEs that have a persistent identifier. The entity domain to which the ANEs belong is "self-defined" and valid only within the property map.

```
GET /directory HTTP/1.1
Host: alto.example.com
Accept: application/alto-directory+json,application/alto-error+json

HTTP/1.1 200 OK
Content-Length: 2827
Content-Type: application/alto-directory+json
```

}

```

Figure 8: Example IRD

#### 10.4. Full Property Map Example

The following example uses the properties and IRD defined above in [Section 10.3](#) to retrieve a Property Map for entities with the "ISP" and "ASN" properties.

Note that, to be compact, the response does not include the entity "ipv4:192.0.2.0", because values of all those properties for this entity are inherited from other entities.

Also note that the entities "ipv4:192.0.2.0/28" and "ipv4:192.0.2.16/28" are merged into "ipv4:192.0.2.0/27", because they have the same value of the "ASN" property. The same rule applies to the entities "ipv4:192.0.3.0/28" and "ipv4:192.0.3.0/28". Both of "ipv4:192.0.2.0/27" and "ipv4:192.0.3.0/27" omit the value for the "ISP" property, because it is inherited from "ipv4:192.0.2.0/23".

```
GET /propmap/full/inet-ia HTTP/1.1
Host: alto.example.com
Accept: application/alto-propmap+json,application/alto-error+json
```

```
HTTP/1.1 200 OK
Content-Length: 418
Content-Type: application/alto-propmap+json
```

```
{
  "meta": {
    "dependent-vtags": [
      { "resource-id": "default-network-map",
        "tag": "3ee2cb7e8d63d9fab71b9b34cbf764436315542e" },
      { "resource-id": "alt-network-map",
        "tag": "c0ce023b8678a7b9ec00324673b98e54656d1f6d" }
    ]
  },
  "property-map": {
    "ipv4:192.0.2.0/23": { ".ISP": "BitsRus" },
    "ipv4:192.0.2.0/27": { ".ASN": "12345" },
    "ipv4:192.0.3.0/27": { ".ASN": "12346" }
  }
}
```

#### 10.5. Filtered Property Map Example #1

The following example uses the filtered property map resource to request the "ISP", "ASN" and "state" properties for several IPv4 addresses.

Note that the value of "state" for "ipv4:192.0.2.0" is the only explicitly defined property; the other values are all derived by the inheritance rules for Internet address entities.

```
POST /propmap/lookup/inet-iacs HTTP/1.1
Host: alto.example.com
Accept: application/alto-propmap+json,application/alto-error+json
Content-Length: 158
Content-Type: application/alto-propmapparams+json
```

```
{
  "entities" : [ "ipv4:192.0.2.0",
                 "ipv4:192.0.2.1",
                 "ipv4:192.0.2.17" ],
  "properties" : [ ".ISP", ".ASN", ".state" ]
}
```

```
HTTP/1.1 200 OK
Content-Length: 540
Content-Type: application/alto-propmap+json
```

```
{
  "meta": {
    "dependent-vtags": [
      { "resource-id": "default-network-map",
        "tag": "3ee2cb7e8d63d9fab71b9b34cbf764436315542e" },
      { "resource-id": "alt-network-map",
        "tag": "c0ce023b8678a7b9ec00324673b98e54656d1f6d" }
    ]
  },
  "property-map": {
    "ipv4:192.0.2.0":
      { ".ISP": "BitsRus", ".ASN": "12345", ".state": "PA" },
    "ipv4:192.0.2.1":
      { ".ISP": "BitsRus", ".ASN": "12345", ".state": "NJ" },
    "ipv4:192.0.2.17":
      { ".ISP": "BitsRus", ".ASN": "12345", ".state": "CT" }
  }
}
```

#### 10.6. Filtered Property Map Example #2

The following example uses the filtered property map resource to request the "ASN", "country" and "state" properties for several IPv4 prefixes.

Note that the property values for both entities "ipv4:192.0.2.0/26" and "ipv4:192.0.3.0/26" are not explicitly defined. They are inherited from the entity "ipv4:192.0.2.0/23".

Also note that some entities like "ipv4:192.0.2.0/28" and "ipv4:192.0.2.16/28" in the response are not explicitly listed in the request. The response includes them because they are refinements of the requested entities and have different values for the requested properties.

The entity "ipv4:192.0.4.0/26" is not included in the response, because there are neither entities which it is inherited from, nor entities inherited from it.

```
POST /propmap/lookup/inet-iacs HTTP/1.1
```

```
Host: alto.example.com
```

```
Accept: application/alto-propmap+json,application/alto-error+json
```

```
Content-Length: 170
```

```
Content-Type: application/alto-propmapparams+json
```

```
{
  "entities" : [ "ipv4:192.0.2.0/26",
                 "ipv4:192.0.3.0/26",
                 "ipv4:192.0.4.0/26" ],
  "properties" : [ ".ASN", ".country", ".state" ]
}
```

HTTP/1.1 200 OK  
Content-Length: 766  
Content-Type: application/alto-propmap+json

```
{
  "meta": {
    "dependent-vtags": [
      { "resource-id": "default-network-map",
        "tag": "3ee2cb7e8d63d9fab71b9b34cbf764436315542e" },
      { "resource-id": "alt-network-map",
        "tag": "c0ce023b8678a7b9ec00324673b98e54656d1f6d" }
    ]
  },
  "property-map": {
    "ipv4:192.0.2.0/26": { ".country": "us" },
    "ipv4:192.0.2.0/28": { ".ASN": "12345",
                          ".state": "NJ" },
    "ipv4:192.0.2.16/28": { ".ASN": "12345",
                           ".state": "CT" },
    "ipv4:192.0.2.0": { ".state": "PA" },
    "ipv4:192.0.3.0/26": { ".country": "us" },
    "ipv4:192.0.3.0/28": { ".ASN": "12345",
                          ".state": "TX" },
    "ipv4:192.0.3.16/28": { ".ASN": "12345",
                           ".state": "MN" }
  }
}
```

#### 10.7. Filtered Property Map Example #3

The following example uses the filtered property map resource to request the "default-network-map.pid" property and the "alt-network-map.pid" property for a set of IPv4 addresses and prefixes.

Note that the entity "ipv4:192.0.3.0/27" is decomposed into two entities "ipv4:192.0.3.0/28" and "ipv4:192.0.3.16/28", as they have different "default-network-map.pid" property values.

```
POST /propmap/lookup/pid HTTP/1.1
Host: alto.example.com
Accept: application/alto-propmap+json,application/alto-error+json
Content-Length: 221
Content-Type: application/alto-propmapparams+json
```

```
{
  "entities" : [
    "ipv4:192.0.2.128",
    "ipv4:192.0.2.0/27",
    "ipv4:192.0.3.0/27" ],
  "properties" : [ "default-network-map.pid",
    "alt-network-map.pid ]
}
```

```
HTTP/1.1 200 OK
Content-Length: 774
Content-Type: application/alto-propmap+json
```

```
{
  "meta": {
    "dependent-vtags": [
      {"resource-id": "default-network-map",
       "tag": "3ee2cb7e8d63d9fab71b9b34cbf764436315542e"},
      {"resource-id": "alt-network-map",
       "tag": "c0ce023b8678a7b9ec00324673b98e54656d1f6d"}
    ]
  },
  "property-map": {
    "ipv4:192.0.2.128": { "default-network-map.pid": "defaultpid",
      "alt-network-map.pid": "defaultpid" },
    "ipv4:192.0.2.0/27": { "default-network-map.pid": "pid2",
      "alt-network-map.pid": "pid1" },
    "ipv4:192.0.3.0/28": { "default-network-map.pid": "pid3",
      "alt-network-map.pid": "pid2" },
    "ipv4:192.0.3.16/28": { "default-network-map.pid": "pid4",
      "alt-network-map.pid": "pid2" }
  }
}
```

#### 10.8. Filtered Property Map Example #4

Here is an example of using the filtered property map to query the regions for several PIDs in "default-network-map". The "region" property is specified as a "self-defined" property, i.e., the values of this property are defined by this property map resource.

```
POST /propmap/lookup/region HTTP/1.1
Host: alto.example.com
Accept: application/alto-propmap+json,application/alto-error+json
Content-Length: 132
Content-Type: application/alto-propmapparams+json
```

```
{
  "entities" : ["default-network-map.pid:pid1",
                "default-network-map.pid:pid2"],
  "properties" : [ ".region" ]
}
```

```
HTTP/1.1 200 OK
Content-Length: 326
Content-Type: application/alto-propmap+json
```

```
{
  "meta" : {
    "dependent-vtags" : [
      { "resource-id": "default-network-map",
        "tag": "7915dc0290c2705481c491a2b4ffbec482b3cf62" }
    ]
  },
  "property-map": {
    "default-network-map.pid:pid1": {
      ".region": "us-west"
    },
    "default-network-map.pid:pid2": {
      ".region": "us-east"
    }
  }
}
```

#### 10.9. Filtered Property Map for ANEs Example #5

The following example uses the filtered property map resource "ane-dc-property-map" to request properties "storage-capacity" and "cpu" on several ANEs defined in this property map.

```
POST /propmap/lookup/ane-dc HTTP/1.1
Host: alto.example.com
Accept: application/alto-propmap+json,application/alto-error+json
Content-Length: 155
Content-Type: application/alto-propmapparams+json
```

```
{
  "entities" : [ ".ane:dc21",
                  ".ane:dc45.srv9",

## 11. Security Considerations

Both Property Map and Filtered Property Map defined in this document fit into the architecture of the ALTO base protocol, and hence the Security Considerations ([Section 15 of \[RFC7285\]](#)) of the base protocol fully apply: authenticity and integrity of ALTO information (i.e., authenticity and integrity of Property Maps), potential undesirable guidance from authenticated ALTO information (e.g., potentially imprecise or even wrong value of a property such as geo-location), confidentiality of ALTO information (e.g., exposure of a potentially sensitive entity property such as geo-location), privacy for ALTO users, and availability of ALTO services should all be considered.

ALTO clients using this extension should in addition be aware that the entity properties they require may convey more details than the endpoint properties conveyed by using [\[RFC7285\]](#). Client requests may reveal details on their activity or plans thereof, that a malicious

usage may monetize or use for attacks or undesired surveillance. Likewise, ALTO Servers expose entities and properties related to specific parts of the infrastructure that reveal details on capabilities, locations, or resource availability. These details may be maliciously used for competition purposes, or to cause resources shortage or undesired publication.

To address these concerns, the Property Maps provided by this extension require additional attention on two security considerations discussed in [RFC7285]: "potential undesirable guidance from authenticated ALTO information" (Section 15.2 of [RFC7285]) and "confidentiality of ALTO information" (Section 15.3 of [RFC7285]). Threats to the availability of the ALTO Service caused by highly demanding queries should be addressed as specified in Section 15.5 of [RFC7285].

- \* Potential undesirable guidance from authenticated ALTO information: it can be caused by Property values that change over time and thus lead to performance degradation or system rejection of application requests.

To avoid these consequences, a more robust ALTO client should adopt and extend protection strategies specified in Section 15.2 of [RFC7285]. For example, to be notified immediately when a particular ALTO value that the Client depends on changes, it is RECOMMENDED that both the ALTO Client and ALTO Server using this extension implement "Application-Layer Traffic Optimization (ALTO) Incremental Updates Using Server-Sent Events (SSE)" [RFC8895].

- \* Confidentiality of ALTO information: as discussed in Section 15 of [RFC7285], properties may have sensitive customer-specific information. If this is the case, an ALTO Server may limit access to those properties by providing several different property maps. For non-sensitive properties, the ALTO Server would provide a URI which accepts requests from any client. Sensitive properties, on the other hand, would only be available via a secure URI which would require client authentication. Another way is to expose highly abstracted coarse-grained property values to all Clients while restricting access to URIs exposing more fine-grained values to authorized Clients. Restricted access URIs may be gathered in delegate IRDs as specified in Section 9.2.4 of [RFC7285].

Also, while technically this document does not introduce any security risks not inherent in the Endpoint Property Service defined by [RFC7285], the GET-mode property map resource defined in this document does make it easier for a client to download large numbers of property values. Accordingly, an ALTO Server should limit GET-mode property maps to properties that do not contain sensitive data.

Section 12 on IANA considerations of this document specifies that the ALTO service provider MUST be aware of the potential sensitiveness of exposed entity domains and properties.

Section 12.2.2. (ALTO Entity Domain Type Registration Process) of this document specifies that when the registration of an entity domain type is requested at the IANA, the request MUST include security considerations that show awareness of how the exposed entity addresses may be related to private information about an ALTO client or an infrastructure service provider. Likewise, Section 12.3. (ALTO Entity Property Type Registry) of this document specifies that when the registration of a property type is requested at the IANA, the request MUST include security considerations that explain why this property type is required for ALTO-based operations.

The risk of ALTO information being leaked to malicious Clients or third parties is addressed similarly to in Section 7 of [RFC8896]. ALTO Clients and Servers SHOULD support both TLS 1.3 [RFC8446] and TLS 1.2 [RFC5246] and MAY support and use newer versions of TLS as long as the negotiation process succeeds.

## 12. IANA Considerations

This document defines additional application/alto-\* media types. It defines an ALTO Entity Domain Type Registry that extends the ALTO Address Type Registry defined in [RFC7285]. It also defines an ALTO Entity Property Type Registry that extends the ALTO endpoint property registry defined in [RFC7285].

### 12.1. application/alto-\* Media Types

This document registers two additional ALTO media types, listed in Table 1.

Type	Subtype	Specification
application	alto-propmap+json	<a href="#">Section 7.1</a>
application	alto-propmapparams+json	<a href="#">Section 8.3</a>

Table 1: Additional ALTO Media Types.

## Type name:

application

## Subtype name:

This document registers multiple subtypes, as listed in Table 1.

## Required parameters:

n/a

## Optional parameters:

n/a

## Encoding considerations:

Encoding considerations are identical to those specified for the "application/json" media type. See [\[RFC8259\]](#).

## Security considerations:

Security considerations related to the generation and consumption of ALTO Protocol messages are discussed in [Section 15 of \[RFC7285\]](#).

## Interoperability considerations:

This document specifies formats of conforming messages and the interpretation thereof.

## Published specification:

This document is the specification for these media types; see Table 1 for the section documenting each media type.

## Applications that use this media type:

ALTO servers and ALTO clients either stand alone or are embedded within other applications.

## Additional information:

Magic number(s): n/a

File extension(s): This document uses the mime type to refer to protocol messages and thus does not require a file extension.

Macintosh file type code(s): n/a

Person & email address to contact for further information:  
See Authors' Addresses section.

Intended usage:  
COMMON

Restrictions on usage:  
n/a

Author:  
See Authors' Addresses section.

Change controller:  
Internet Engineering Task Force (mailto:iesg@ietf.org).

## 12.2. ALTO Entity Domain Type Registry

This document requests IANA to create and maintain the "ALTO Entity Domain Type Registry", listed in Table 2.

Identifier	Entity Identifier Encoding	Hierarchy & Inheritance	Media Type of Defining Resource
ipv4	See Section 6.1.1	See Section 6.1.3	application/alto-networkmap+json
ipv6	See Section 6.1.2	See Section 6.1.3	application/alto-networkmap+json
pid	See Section 6.2	None	application/alto-networkmap+json

Table 2: ALTO Entity Domain Types

This registry serves two purposes. First, it ensures uniqueness of identifiers referring to ALTO entity domain types. Second, it states the requirements for allocated entity domain types.

#### 12.2.1. Consistency Procedure between ALTO Address Type Registry and ALTO Entity Domain Type Registry

One potential issue of introducing the "ALTO Entity Domain Type Registry" is its relationship with the "ALTO Address Types Registry" already defined in [Section 14.4 of \[RFC7285\]](#). In particular, the entity identifier of a type of an entity domain registered in the "ALTO Entity Domain Type Registry" MAY match an address type defined in "ALTO Address Type Registry". It is necessary to precisely define and guarantee the consistency between "ALTO Address Type Registry" and "ALTO Entity Domain Registry".

We define that the ALTO Entity Domain Type Registry is consistent with ALTO Address Type Registry if two conditions are satisfied:

- \* When an address type is already or able to be registered in the ALTO Address Type Registry [[RFC7285](#)], the same identifier MUST be used when a corresponding entity domain type is registered in the ALTO Entity Domain Type Registry.
- \* If an ALTO entity domain type has the same identifier as an ALTO address type, their addresses encoding MUST be compatible.

To achieve this consistency, the following items MUST be checked before registering a new ALTO entity domain type in a future document:

- \* Whether the ALTO Address Type Registry contains an address type that can be used as an identifier for the candidate entity domain type identifier. This has been done for the identifiers "ipv4" and "ipv6" of Table 2.
- \* Whether the candidate entity domain type identifier can potentially be an endpoint address type, as defined in Sections 2.1 and 2.2 of [[RFC7285](#)].

When a new ALTO entity domain type is registered, the consistency with the ALTO Address Type Registry MUST be ensured by the following procedure:

- \* Test: Do corresponding entity domain type identifiers match a known "network" address type?
  - If yes (e.g., cell, MAC or socket addresses):
    - o Test: Is such an address type present in the ALTO Address Type Registry?

- + If yes: Set the new ALTO entity domain type identifier to be the found ALTO address type identifier.
- + If no: Define a new ALTO entity domain type identifier and use it to register a new address type in the ALTO Address Type Registry following [Section 14.4 of \[RFC7285\]](#).
- o Use the new ALTO entity domain type identifier to register a new ALTO entity domain type in the ALTO Entity Domain Type Registry following [Section 12.2.2](#) of this document.
- If no (e.g., pid name, ane name or country code): Proceed with the ALTO Entity Domain Type registration as described in [Section 12.2.2](#).

#### 12.2.2. ALTO Entity Domain Type Registration Process

New ALTO entity domain types are assigned after IETF Review [\[RFC8126\]](#) to ensure that proper documentation regarding the new ALTO entity domain types and their security considerations has been provided. RFCs defining new entity domain types SHOULD indicate how an entity in a registered type of domain is encoded as an EntityID, and, if applicable, the rules defining the entity hierarchy and property inheritance. Updates and deletions of ALTO entity domains types follow the same procedure.

Registered ALTO entity domain type identifiers MUST conform to the syntactical requirements specified in [Section 5.1.2](#). Identifiers are to be recorded and displayed as strings.

Requests to the IANA to add a new value to the Entity Domain Type registry MUST include the following information:

- \* Identifier: The name of the desired ALTO entity domain type.
- \* Entity Identifier Encoding: The procedure for encoding the identifier of an entity of the registered domain type as an EntityID (see [Section 5.1.3](#)). If corresponding entity identifiers of an entity domain type match a known "network" address type, the Entity Identifier Encoding of this domain identifier MUST include both Address Encoding and Prefix Encoding of the same identifier registered in the ALTO Address Type Registry [\[RFC7285\]](#). To define properties, an individual entity identifier and the corresponding full-length prefix MUST be considered aliases for the same entity.
- \* Hierarchy: If the entities form a hierarchy, the procedure for determining that hierarchy.

- \* Inheritance: If entities can inherit property values from other entities, the procedure for determining that inheritance.
- \* Media type of defining information resource: Some entity domain types allow an entity domain name to be combined with an information resource name to define a resource-specific entity domain. Such an information resource is called "defining information resource". In this case, the authorized media type of the defining information resources MUST be unique and MUST be specified in the document defining the entity domain type. When an entity domain type allows combinations with defining resources, this MUST be indicated here, together with the authorized media type for the defining resources. The defining information resource for a resource-specific entity domain is the one that:
  - has an entry in the IRD,
  - defines these entities,
  - does not use another information resource that defines these entities,
  - defines and exposes entity identifiers that are all persistent.
  - has a unique media type equal to the one specified in the document defining the entity domain type.
- \* Knowing the media type of the defining information resource is useful when Servers indicate resource specific entity domains in the property map capabilities. Clients need to know if the combination of information resource type and entity domain type is allowed. See also, [Section 4.6](#) and [Section 5.1](#) for more information.
- \* Mapping to ALTO Address Type: A boolean value to indicate if the entity domain type can be mapped to the ALTO address type with the same identifier.
- \* Security Considerations: In some usage scenarios, entity identifiers carried in ALTO Protocol messages may reveal information about an ALTO client or an ALTO service provider. Applications and ALTO service providers using addresses of the registered type should be cognizant of how (or if) the addressing scheme relates to private information and network proximity.

This specification requests registration of the identifiers "ipv4", "ipv6" and "pid", as shown in Table 2.

### 12.3. ALTO Entity Property Type Registry

This document requests IANA to create and maintain the "ALTO Entity Property Type Registry", listed in Table 3.

This registry extends the "ALTO Endpoint Property Type Registry", defined in [RFC7285], in that a property type is defined on one or more entity domains, rather than just on IPv4 and IPv6 Internet address domains. An entry in this registry is an ALTO entity property type defined in Section 5.2.1. Thus, a registered ALTO entity property type identifier MUST conform to the syntactical requirements specified in that section.

Identifier	Intended Semantics	Media Type of Defining Resource
pid	See Section 7.1.1 of [RFC7285]	application/alto- networkmap+json

Table 3: ALTO Entity Property Types.

Requests to the IANA to add a new value to the registry MUST include the following information:

- \* Identifier: The unique id for the desired ALTO entity property type. The format MUST be as defined in Section 5.2.1 of this document. It includes the information of the applied ALTO entity domain and the property name.
- \* Intended Semantics: ALTO entity properties carry with them semantics to guide their usage by ALTO clients. Hence, a document defining a new type SHOULD provide guidance to both ALTO service providers and applications utilizing ALTO clients as to how values of the registered ALTO entity property should be interpreted.
- \* Media type of defining information resource: when the property type allows values to be defined relatively to a given information resource, the latter is referred to as the "defining information resource", see also description in Section 4.7. The media type of the possibly used defining information resource MUST be unique and MUST be specified here, as well as in the document that defines the property type.

- \* Security Considerations: ALTO entity properties expose information to ALTO clients. ALTO service providers should be cognizant of the security ramifications related to the exposure of an entity property.

In security considerations, the request should also discuss the sensitivity of the information, and why it is required for ALTO-based operations. Regarding this discussion, the request SHOULD follow the recommendations of [Section 14.3](#). ALTO Endpoint Property Type Registry in [\[RFC7285\]](#).

This document requests registration of the identifier "pid", listed in Table 3. Semantics for this property are documented in [Section 7.1.1 of \[RFC7285\]](#). No security issues related to the exposure of a "pid" identifier are considered, as it is exposed with the Network Map Service defined and mandated in [\[RFC7285\]](#).

### 13. Acknowledgments

The authors would like to thank Dawn Chen (Tongji University), and Shenshen Chen (Tongji/Yale University) for their contributions to earlier drafts. Thank you also to Qiao Xiang (Yale University), Shawn Lin, Xin Wang and Vijay Gurbani (Vail systems) for fruitful discussions. Last, big thanks to Danny Perez (University of Campinas) and Luis Contreras (Telefonica) for their substantial review feedback and suggestions to improve this document.

## [Appendix A.](#) Features introduced with the Entity Property Maps extension

The Entity Property Maps extension described in this document introduces a number of features that are summarized in table below. The first column provides the name of the feature. The second column provides the section number of this document that gives a high level description of the feature. The third column provides the section number of this document that gives a normative description relating to the feature, when applicable.

Feature	High-level description	Related normative description
Entity	<a href="#">Section 3.1</a>	<a href="#">Section 5.1.3</a>
Entity domain (ED)	<a href="#">Section 3.2</a>	
Entity domain type	Section 3.2.1	<a href="#">Section 5.1.1</a>
Entity domain name	Section 3.2.2	<a href="#">Section 5.1.2</a>
Entity property (EP) type	<a href="#">Section 3.3</a>	<a href="#">Section 5.2</a> , <a href="#">Section 5.2.1</a> , <a href="#">Section 5.2.2</a> , <a href="#">Section 5.2.3</a>
Entity property map	<a href="#">Section 3.4</a>	<a href="#">Section 7</a> , <a href="#">Section 8</a>
Resource-specific ED name	<a href="#">Section 4.2</a>	<a href="#">Section 5.1.2</a> , <a href="#">Section 5.1.2.1</a>
Resource-specific EP value	<a href="#">Section 4.3</a>	<a href="#">Section 5.2.3</a>
Entity Hierarchy and property inheritance	<a href="#">Section 4.4</a>	<a href="#">Section 5.1.4</a>
Defining information resource	Section 4.6, <a href="#">Section 4.7</a>	<a href="#">Section 12.2.2</a> , <a href="#">Section 12.3</a>

Table 4: Features introduced with ALTO Entity Property Maps
