Yang Data Model for BGP/MPLS L3 VPNs
draft-ietf-bess-l3vpn-yang-04.txt

Abstract

This document defines a YANG data model that can be used to configure and manage BGP Layer 3 VPNs.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at https://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on April 22, 2019.

1. Introduction

YANG [RFC6020] is a data definition language that was introduced to define the contents of a conceptual data store that allows networked devices to be managed using NETCONF [RFC6241]. YANG is proving relevant beyond its initial confines, as bindings to other interfaces (e.g. ReST) and encodings other than XML (e.g. JSON) are being defined. Furthermore, YANG data models can be used as the basis of implementation for other interfaces, such as CLI and programmatic APIs.

This document defines a YANG model that can be used to configure and manage BGP L3VPNs [RFC4364]. It contains VRF specific parameters as well as BGP specific parameters applicable for L3VPNs. The individual containers defined in this model contain control knobs for configuration for that purpose, as well as a few data nodes that can be used to monitor health and gather statistics.

1.1. Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC 2119 [RFC2119].

2. Definitions and Acronyms

AF: Address Family

AS: Autonomous System

ASBR: Autonomous System Border Router

BGP: Border Gateway Protocol

CE: Customer Edge

PE: Provider Edge

L3VPN: Layer 3 VPN
3. Design of BGP L3VPN Data Model

3.1. Overview

There are two parts of the BGP L3VPN yang data model. The first part of the model defines VRF specific parameters for L3VPN by augmenting the network-instance container defined in the network instance model [I-D.ietf-rtgwg-ni-model] and the second part of the model defines BGP specific parameters for the L3VPN by augmenting the base BGP data model defined in [I-D.ietf-idr-bgp-model].

3.2. VRF Specific Configuration

IETF network instance model defines various ni-types, one of which is l3vpn. This provides an anchor point to add a new container l3vpn. Under this container per VPN parameters pertaining to L3VPN are added.

3.2.1. VRF interface

To associate a VRF instance with an interface, bind-network-instance config should be used. This is covered in the base network instance model [I-D.ietf-rtgwg-ni-model].

3.2.2. Route distinguisher

Route distinguisher (RD) is an unique identifier used in VPN routes to distinguish prefixes across different VPNs. RD is 8 byte field as defined in the [RFC4364]. Where the first two bytes refer to type followed by 6 bytes of value. The format of the value is dependent on type. In the yang model, RD is defined under l3vpn container under a network-instance. Yang datatype for RD is imported from [RFC8294].
3.2.3. Import and export route targets

Route-target (RT) is an extended community used to specify the rules for importing and exporting the routes for each VRF as defined in [RFC4364]. This is applicable in the context of an address-family under the VRF. Under the l3vpn container, statements for import and export route-targets are added for ipv4 and ipv6 address family. Both import and export sets are modeled as a list of rout-targets, yang datatype for which is imported from [RFC8294]. An import rule is modeled as list of RTs or a leafref to the route policy [I-D.ietf-rtgwg-policy-model] specifying the list of RTs to be matched for importing the routes into the VRF. Similarly, an export rule is modeled as a list of RTs or a leafref the route policy [I-D.ietf-rtgwg-policy-model] specifying the list of RTs which should be attached to routes exported from the VRF. In the case where policy is used to specify the RTs, a reference to the policy via leafref is used in this model, but actual definition of policy is outside the scope of this document. In addition, this section also defines parameters for the import from global routing table and export to global routing table, as well as route limit per VPN instance for ipv4 and ipv6 address family.

3.2.4. Forwarding mode

This configuration augments interface list under interface container under a network instance as defined in IETF network instance model [I-D.ietf-rtgwg-ni-model]. Forwarding mode configuration is required under the ASBR facing interface to enable mpls forwarding for directly connected BGP peers for inter-as option B peering.

3.2.5. Label security

For inter-as option-B peering across ASs, under the ASBR facing interface, mpls label security enables the checks for RPF label on incoming packets. Ietf-interface container is augmented to add this config.

3.2.6. Yang tree
3.3. BGP Specific Configuration

The BGP specific configuration for L3VPNs is defined by augmenting base BGP model [I-D.ietf-idr-bgp-model]. In particular, specific knobs are added under neighbor and address family containers to handle VPN routes and ASBR peering.
3.3.1. VPN peering

For peering between PE routers, specific VPN address family needs to be enabled under BGP container in the context of core instance. Base BGP draft [I-D.ietf-idr-bgp-model] has l3vpn address family in the list of identity refs for AFs under global and neighbor modes. The same is augmented here for additional knobs. For peering with CE routers the VRF specific BGP configurations such as neighbors and address-family are covered in base BGP config, except that such configuration will be in the context of a VRF. The instance of BGP in this case would be a separate instance in the context of vrf-root as defined in [I-D.ietf-rtgwg-ni-model].

3.3.2. VPN prefix limits

Limits for max number of VPN prefixes for a PE router is defined in the context of VPN address family under BGP. This would be the total number of prefixes in VPN table per AF in the context of BGP protocol. Route table limit for ipv4 and ipv6 address family for each VPN instance is also defined under BGP. The total prefix limit per VPN, including all the protocols is defined in the context of VRF address family under routing instance.

3.3.3. Label Mode

Label mode knobs control the label allocation behavior for VRF routes. Such as to specify Per-site, Per-vpn and Per-route label allocation. These knobs augment BGP global AF containers in the context of default routing instance.

3.3.4. ASBR options

This includes few specific knobs for ASBR peering methods illustrated in [RFC4364]. Such as route target retention on ASBRs for inter-as VPN peering across ASBRs with option-B method. Appropriate containers under BGP AF are augmented.

3.3.5. Yang tree
module: ietf-bgp-l3vpn

augment /bgp:bgp/bgp:global/bgp:afi-safis/bgp:afi-safi/bgp:l3vpn-ipv4-unicast:

// TBD Additional oper state leafs

// TBD RPCs

<CODE ENDS>
5. IANA Considerations

6. Security Considerations

The transport protocol used for sending the BGP L3VPN data MUST support authentication and SHOULD support encryption. The data-model by itself does not create any security implications.

This draft does not change any underlying security issues inherent in [I-D.ietf-rtgwg-ni-model] and [I-D.ietf-idr-bgp-model].

7. Acknowledgements

The authors would like to thank TBD for their detail reviews and comments.
