YANG Alarm Module
draft-ietf-ccamp-alarm-module-09

Abstract

This document defines a YANG module for alarm management. It includes functions for alarm list management, alarm shelving and notifications to inform management systems. There are also operations to manage the operator state of an alarm and administrative alarm procedures. The module carefully maps to relevant alarm standards.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at https://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on October 13, 2019.

1. Introduction

This document defines a YANG [RFC7950] module for alarm management. The purpose is to define a standardized alarm interface for network devices that can be easily integrated into management applications. The model is also applicable as a northbound alarm interface in the management applications.

Alarm monitoring is a fundamental part of monitoring the network. Raw alarms from devices do not always tell the status of the network services or necessarily point to the root cause. However, being able to feed alarms to the alarm management application in a standardized format is a starting point for performing higher level network assurance tasks.

The design of the module is based on experience from using and implementing available alarm standards from ITU [X.733], 3GPP [ALARMIRP] and ANSI [ISA182].

1.1. Terminology and Notation

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [RFC2119] [RFC8174] when, and only when, they appear in all capitals, as shown here.

The following terms are defined in [RFC7950]:

- action
- client
- data tree
- server

The following terms are used within this document:
o Alarm (the general concept): An alarm signifies an undesirable state in a resource that requires corrective action.

o Fault: A fault is the underlying cause of an undesired behavior. There is no trivial one-to-one mapping between faults and alarms. One fault may result in several alarms in case the system lacks root-cause and correlation capabilities. An alarm might not have an underlying fault as a cause. For example, imagine a bad Mean Opinion Score (MOS) alarm from a Voice over IP (VOIP) probe and the cause being non-optimal QoS configuration.

o Alarm Type: An alarm type identifies a possible unique alarm state for a resource. Alarm types are names to identify the state like "link-alarm", "jitter-violation", "high-disk-utilization".

o Resource: A fine-grained identification of the alarming resource, for example: an interface, a process.

o Alarm Instance: The alarm state for a specific resource and alarm type. For example ("GigabitEthernet0/15", link-alarm). An entry in the alarm list.

o Cleared alarm: A cleared alarm is an alarm where the system considers the undesired state to be cleared. Operators can not clear alarms, clearance is managed by the system. For example, a linkUp notification can be considered a clear condition for a linkDown state.

o Closed alarm: Operators can close alarms irrespective of the alarm being cleared or not. A closed alarm indicates that the alarm does not need attention, either since the corrective action has been taken or that it can be ignored for other reasons.

o Alarm Inventory: A list of all possible alarm types on a system.

o Alarm Shelving: Blocking alarms according to specific criteria.

o Corrective Action: An action taken by an operator or automation routine in order to minimize the impact of the alarm or resolve the root cause.

o Management System: The alarm management application that consumes the alarms, i.e., acts as a client.

o System: The system that implements this YANG alarm module, i.e., acts as a server. This corresponds to a network device or a management application that provides a northbound alarm interface.
Tree diagrams used in this document follow the notation defined in [RFC8340].

2. Objectives

The objectives for the design of the Alarm Module are:

- Simple to use. If a system supports this module, it shall be straightforward to integrate this into a YANG based alarm manager.
- View alarms as states on resources and not as discrete notifications.
- To provide a precise definition of "alarm" in order to exclude general events that should not be forwarded as alarm notifications.
- To provide precise identification of alarm types and alarm instances.
- A management system should be able to pull all available alarm types from a system, i.e., read the alarm inventory from a system. This makes it possible to prepare alarm operators with corresponding alarm instructions.
- Address alarm usability requirements, see Appendix G. While IETF and telecom standards have addressed alarms mostly from a protocol perspective, the process industry has published several relevant standards addressing requirements for a useful alarm interface; [EEMUA], [ISA182]. This alarm module defines usability requirements as well as a YANG data model.
- Mapping to [X.733], which is a requirement for some alarm systems. Still, keep some of the X.733 concepts out of the core model in order to make the model small and easy to understand.

3. Alarm Module Concepts

This section defines the fundamental concepts behind the data model. This section is rooted in the works of Vallin et. al [ALARMESEM].

3.1. Alarm Definition

An alarm signifies an undesirable state in a resource that requires corrective action.

There are two main things to remember from this definition:
1. the definition focuses on leaving out events and logging information in general. Alarms should only be used for undesired states that require action.

2. the definition also focuses on alarms as a state on a resource, not the notifications that report the state changes.

See Appendix F for information how this definition relates to other alarm standards.

3.2. Alarm Type

This document defines an alarm type with an alarm type id and an alarm type qualifier.

The alarm type id is modeled as a YANG identity. With YANG identities, new alarm types can be defined in a distributed fashion. YANG identities are hierarchical, which means that a hierarchy of alarm types can be defined.

Standards and vendors should define their own alarm type identities based on this definition.

The use of YANG identities means that all possible alarms are identified at design time. This explicit declaration of alarm types makes it easier to allow for alarm qualification reviews and preparation of alarm actions and documentation.

There are occasions where the alarm types are not known at design time. An example is a system with digital inputs that allows users to connect detectors, such as smoke detectors, to the inputs. In this case it is a configuration action that says that certain connectors are fire alarms for example.

In order to allow for dynamic addition of alarm types the alarm module allows for further qualification of the identity-based alarm type using a string. A potential drawback of this is that there is a significant risk that alarm operators will receive alarm types as a surprise. They do not know how to resolve the problem since a defined alarm procedure does not necessarily exist. To avoid this risk the system MUST publish all possible alarm types in the alarm inventory, see Section 4.2.

A vendor or standards organization can define their own alarm type hierarchy. The example below shows a hierarchy based on X.733 event types:
import ietf-alarms {
  prefix al;
}

identity vendor-alarms {
  base al:alarm-type;
}

identity communications-alarm {
  base vendor-alarms;
}

identity link-alarm {
  base communications-alarm;
}

Alarm types can be abstract. An abstract alarm type is used as a base for defining hierarchical alarm types. Concrete alarm types are used for alarm states and appear in the alarm inventory. There are two kinds of concrete alarm types:

1. The last subordinate identity in the "alarm-type-id" hierarchy is concrete, for example: "alarm-identity.environmental-alarm.smoke". In this example "alarm-identity" and "environmental-alarm" are abstract YANG identities, whereas "smoke" is a concrete YANG identity.

2. The YANG identity hierarchy is abstract and the concrete alarm type is defined by the dynamic alarm qualifier string, for example: "alarm-identity.environmental-alarm.external-detector" with alarm-type-qualifier "smoke".

For example:
// Alternative 1: concrete alarm type identity
import ietf-alarms {
    prefix al;
}
identity environmental-alarm {
    base al:alarm-type;
    description "Abstract alarm type";
}
identity smoke {
    base environmental-alarm;
    description "Concrete alarm type";
}

// Alternative 2: concrete alarm type qualifier
import ietf-alarms {
    prefix al;
}
identity environmental-alarm {
    base al:alarm-type;
    description "Abstract alarm type";
}
identity external-detector {
    base environmental-alarm;
    description "Abstract alarm type, a run-time configuration procedure sets the type of alarm detected. This will be reported in the alarm-type-qualifier.";
}

A server SHOULD strive to minimize the number of dynamically defined alarm types.

3.3. Identifying the Alarming Resource

It is of vital importance to be able to refer to the alarming resource. This reference must be as fine-grained as possible. If the alarming resource exists in the data tree then an instance-identifier MUST be used with the full path to the object.

When the module is used in a controller/orchestrator/manager the original device resource identification can be modified to include the device in the path. The details depend on how devices are identified, and are out of scope for this specification.

Example:

The original device alarm might identify the resource as "/dev:interfaces/dev:interface[dev:name='FastEthernet1/0']".
The resource identification in the manager could look something like: 
"/mgr:devices/mgr:device[mgr:name='xyz123']/dev:interfaces/
dev:interface[dev:name='FastEthernet1/0']"

This module also allows for alternate naming of the alarming resource
if it is not available in the data tree.

### 3.4. Identifying Alarm Instances

A primary goal of this alarm module is to remove any ambiguity in how
alarm notifications are mapped to an update of an alarm instance.
The X.733 and 3GPP documents were not clear on this point. This YANG
alarm module states that the tuple (resource, alarm type identifier,
alarm type qualifier) corresponds to a single alarm instance. This
means that alarm notifications for the same resource and same alarm
type are matched to update the same alarm instance. These three
leafs are therefore used as the key in the alarm list:

```yaml
list alarm {
  key "resource alarm-type-id alarm-type-qualifier";
  ...
}
```

### 3.5. Alarm Lifecycle

The alarm model clearly separates the resource alarm lifecycle from
the operator and administrative lifecycles of an alarm.

- **resource alarm lifecycle**: the alarm instrumentation that controls
  alarm raise, clearance, and severity changes.

- **operator alarm lifecycle**: operators acting upon alarms with
  actions like acknowledgment and closing. Closing an alarm implies
  that the operator considers the corrective action performed.
  Operators can also shelf (block/filter) alarms in order to avoid
  nuisance alarms.

- **administrative alarm lifecycle**: purging (deleting) unwanted alarms
  and compressing the alarm status change list. This module exposes
  operations to manage the administrative lifecycle. The server may
  also perform these operations based on other policies, but how
  that is done is out of scope for this document.

A server **SHOULD** describe how long it retains cleared/closed alarms:
until manually purged or if it has an automatic removal policy. How
this is done is outside the scope of this document.
3.5.1. Resource Alarm Lifecycle

From a resource perspective, an alarm can for example have the following lifecycle: raise, change severity, change severity, clear, being raised again, etc. All of these status changes can have different alarm texts generated by the instrumentation. Two important things to note:

1. Alarms are not deleted when they are cleared. Deleting alarms is an administrative process. The alarm module defines an action "purge-alarms" that deletes alarms.

2. Alarms are not cleared by operators, only the underlying instrumentation can clear an alarm. Operators can close alarms.

The YANG tree representation below illustrates the resource oriented lifecycle:

```
+--ro alarm* [resource alarm-type-id alarm-type-qualifier]
    ... 
    +--ro is-cleared boolean
    +--ro last-changed yang:date-and-time
    +--ro perceived-severity severity
    +--ro alarm-text alarm-text
    +--ro status-change* [time] {alarm-history}?
        +--ro time yang:date-and-time
        +--ro perceived-severity severity-with-clear
        +--ro alarm-text alarm-text
```

For every status change from the resource perspective a row is added to the "status-change" list, if the server implements the feature "alarm-history". The feature "alarm-history" is optional to implement, since keeping the alarm history may have an impact on the server's memory resources.

The last status values are also represented as leafs for the alarm. Note well that the alarm severity does not include "cleared", alarm clearance is a boolean flag.

An alarm can therefore look like this: ("GigabitEthernet0/25", link-alarm,"")", false, 2018-04-08T08:20:10.00Z, major, "Interface GigabitEthernet0/25 down")

3.5.2. Operator Alarm Lifecycle

Operators can act upon alarms using the set-operator-state action:
The operator state for an alarm can be: "none", "ack", "shelved", and "closed". Alarm deletion (using the action "purge-alarms") can use this state as a criterion. For example, a closed alarm is an alarm where the operator has performed any required corrective actions. Closed alarms are good candidates for being purged.

3.5.3. Administrative Alarm Lifecycle

Deleting alarms from the alarm list is considered an administrative action. This is supported by the "purge-alarms" action. The "purge-alarms" action takes a filter as input. The filter selects alarms based on the operator and resource lifecycle such as "all closed cleared alarms older than a time specification". The server may also perform these operations based on other policies, but how that is done is out of scope for this document.

Purged alarms are removed from the alarm list. Note well, if the alarm resource state changes after a purge, the alarm will reappear in the alarm list.

Alarms can be compressed. Compressing an alarm deletes all entries in the alarm's "status-change" list except for the last status change. A client can perform this using the "compress-alarms" action. The server may also perform these operations based on other policies, but how that is done is out of scope for this document.

3.6. Root Cause, Impacted Resources and Related Alarms

The alarm module does not mandate any requirements for the system to support alarm correlation or root-cause and service-impact analysis. However, if such features are supported, this section describes how the results of such analysis are represented in the data model. These parts of the model are optional. The module supports three scenarios:
Root cause analysis: An alarm can indicate candidate root cause resources, for example: a database issue alarm referring to a full disc partition.

Service impact analysis: An alarm can refer to potential impacted resources, for example: an interface alarm referring to impacted network services

Alarm correlation: Dependencies between alarms, several alarms can be grouped as relating to each other, for example a streaming media alarm relating to a high jitter alarm.

Different systems have varying degrees of alarm correlation and analysis capabilities, and the intent of the alarm module is to enable any capability, including none.

The general principle of this alarm module is to limit the amount of alarms. In many cases several resources are affected for a given underlying problem. A full disk will of course impact databases and applications as well. The recommendation is to have a single alarm for the underlying problem and list the affected resources in the alarm, rather than having separate alarms for each resource.

The alarm has one leaf-list to identify possible "impacted-resources" and a leaf-list to identify possible "root-cause-resources". These serves as hints only. It is up to the client application to use this information to present the overall status. Using the disk full example, a good alarm would be to use the hard disk partition as the alarming resource and add the database and applications into the "impacted-resources" leaf-list.

A system should always strive to identify the resource that can be acted upon as the "resource" leaf. The "impacted-resource" leaf-list shall be used to identify any side-effects of the alarm. The impacted resources can not be acted upon to fix the problem. The disk full example above illustrates the principle; you can not fix the underlying issue by database operations. However, you need to pay attention to the database to perform any operations that limits the impact of problem.

On some occasions the system might not be capable of detecting the root cause, the resource that can be acted upon. The instrumentation in this case only monitors the side-effect and raises an alarm to indicate a situation requiring attention. The instrumentation still might identify possible candidates for the root-cause resource. In this case the "root-cause-resource" leaf-list can be used to indicate the candidate root-cause resources. An example of this kind of alarm might be an active test tool that detects an SLA violation on a VPN.
connection and identifies the devices along the chain as candidate root causes.

The alarm module also supports a way to associate different alarms to each other with the "related-alarm" list. This list enables the server to inform the client that certain alarms are related to other alarms.

Note well that this module does not prescribe any dependencies or preference between the above alarm correlation mechanisms. Different systems have different capabilities and the above described mechanisms are available to support the instrumentation features.

3.7. Alarm Shelving

Alarm shelving is an important function in order for alarm management applications and operators to stop superfluous alarms. A shelved alarm implies that any alarms fulfilling these criteria are ignored (blocked/filtered). Shelved alarms appear in a dedicated shelved alarm list in order to be filtered out from the alarm list in order for the main alarm list to only contain entries of interest. Shelved alarms do not generate notifications but the shelved alarm list is updated with any alarm state changes.

Alarm shelving is optional to implement, since matching alarms against shelf criteria may have an impact on the server’s processing resources.

3.8. Alarm Profiles

Alarm profiles are used to configure further information to an alarm type. This module supports configuring severity levels overriding the system default levels. This corresponds to the Alarm Assignment Profile, ASAP, functionality in M.3100 [M.3100] and M.3160 [M.3160]. Other standard or enterprise modules can augment this list with further alarm type information.

4. Alarm Data Model

The fundamental parts of the data model are the "alarm-list" with associated notifications and the "alarm-inventory" list of all possible alarm types. These MUST be implemented by a system. The rest of the data model are made conditional with the YANG features "operator-actions", "alarm-shelving", "alarm-history", "alarm-summary", "alarm-profile", and "severity-assignment".

The data model has the following overall structure:
YANG Alarm Module

+-rw control
  |  +--rw max-alarm-status-changes?  union
  |  +--rw notify-status-changes?     enumeration
  |  +--rw notify-severity-level?    severity
  |  +--rw alarm-shelving {alarm-shelving}?
  |     ...
+-ro alarm-inventory
  |  +--ro alarm-type* [alarm-type-id alarm-type-qualifier]
  |     ...
+-ro summary {alarm-summary}?
  |  +--ro alarm-summary* [severity]
  |     ...
  |  +--ro shelves-active?  empty {alarm-shelving}?
+-ro alarm-list
  |  +--ro number-of-alarms?  yang:gauge32
  |  +--ro last-changed?     yang:date-and-time
  |  +--ro alarm* [resource alarm-type-id alarm-type-qualifier]
  |     ...
  |     +--x purge-alarms
  |     ...
  |     +--x compress-alarms {alarm-history}?
  |     ...
  +--ro shelved-alarms {alarm-shelving}?
    |  +--ro number-of-shelved-alarms?  yang:gauge32
    |  +--ro shelved-alarms-last-changed?  yang:date-and-time
    |  +--ro shelved-alarm* [resource alarm-type-id alarm-type-qualifier]
    |     ...
    |     +--x purge-shelved-alarms
    |     ...
    |     +--x compress-shelved-alarms {alarm-history}?
    |     ...
+-rw alarm-profile*
  |  [alarm-type-id alarm-type-qualifier-match resource]
  |     (alarm-profile)?
  |     +--rw alarm-type-id  alarm-type-id
  |     +--rw alarm-type-qualifier-match  string
  |     +--rw resource  resource-match
  |     +--rw description  string
  |     +--rw alarm-severity-assignment-profile (severity-assignment)?
4.1. Alarm Control

The "/alarms/control/notify-status-changes" leaf controls if notifications are sent for all state changes, only raise and clear, or only notifications more severe than a configured level. This feature in combination with alarm shelving corresponds to the ITU Alarm Report Control functionality, see Appendix F.2.4.

Every alarm has a list of status changes. The length of this list is controlled by "/alarms/control/max-alarm-status-changes". When the list is full and a new entry created, the oldest entry is removed.

4.1.1. Alarm Shelving

The shelving control tree is shown below:

```
  +--rw control
    +--rw alarm-shelving {alarm-shelving}?
      +--rw shelf* [name]
        +--rw name          string
          +--rw resource*    resource-match
          +--rw alarm-type*   
            |                   [alarm-type-id alarm-type-qualifier-match]
            |                   +--rw alarm-type-id  alarm-type-id
            |                   +--rw alarm-type-qualifier-match  string
            +--rw description? string
```

Shelved alarms are shown in a dedicated shelved alarm list. Matching alarms MUST appear in the /alarms/shelved-alarms/shelved-alarm list, and non-matching /alarms MUST appear in the /alarms/alarm-list/alarm list. The server does not send any notifications for shelved alarms.

Shelving and unshelving can only be performed by editing the shelf configuration. It cannot be performed on individual alarms. The server will add an operator state indicating that the alarm was shelved/unshelved.

A leaf (/alarms/summary/shelves-active) in the alarm summary indicates if there are shelved alarms.

A system can select to not support the shelving feature.

4.2. Alarm Inventory

The alarm inventory represents all possible alarm types that may occur in the system. A management system may use this to build alarm procedures. The alarm inventory is relevant for several reasons:
The system might not implement all defined alarm type identities, and some alarm identities are abstract.

The system has configured dynamic alarm types using the alarm qualifier. The inventory makes it possible for the management system to discover these.

Note that the mechanism whereby dynamic alarm types are added using the alarm type qualifier MUST populate this list.

The optional leaf-list "resource" in the alarm inventory enables the system to publish for which resources a given alarm type may appear.

A server MUST implement the alarm inventory in order to enable controlled alarm procedures in the client.

A server implementer may want to document the alarm inventory for off-line processing by clients. The file format defined in [I-D.ietf-netmod-yang-instance-file-format] can be used for this purpose.

The alarm inventory tree is shown below:

```
+--ro alarm-inventory
    +--ro alarm-type* [alarm-type-id alarm-type-qualifier]
        +--ro alarm-type-id          alarm-type-id
        +--ro alarm-type-qualifier   alarm-type-qualifier
        +--ro resource*              resource-match
        +--ro will-clear              boolean
        +--ro severity-levels*        severity
        +--ro description             string
```

4.3. Alarm Summary

The alarm summary list summarizes alarms per severity; how many cleared, cleared and closed, and closed. It also gives an indication if there are shelved alarms.

The alarm summary tree is shown below:
4.4. The Alarm List

The alarm list (/alarms/alarm-list) is a function from the tuple (resource, alarm type, alarm type qualifier) to the current composite alarm state. The composite state includes states for the resource lifecycle such as severity, clearance flag and operator states such as acknowledgment. This means that for a given resource and alarm type the alarm list shows the current states of the alarm such as acknowledged and cleared status.

---ro alarm-list
  +--ro number-of-alarms?   yang:gauge32
  +--ro last-changed?       yang:date-and-time
  +--ro alarm* [resource alarm-type-id alarm-type-qualifier]
    |  +--ro resource                 resource
    |  +--ro alarm-type-id            alarm-type-id
    |  +--ro alarm-type-qualifier     alarm-type-qualifier
    |  +--ro alt-resource*            resource
    |  +--ro related-alarm* [resource alarm-type-id alarm-type-qualifier]
    |    |    |  [alarm-correlation]?             
    |    |    ++--ro resource
    |    |    |    |    |    | -> /alarms/alarm-list/alarm/resource
    |    |    |    |    ++ro alarm-type-id  leafref
    |    |    |    |    ++ro alarm-type-qualifier  leafref
    |    |    |  +--ro impacted-resource* resource
    |    |    |    |    |    | {service-impact-analysis}?  
    |    |    |    |    |    | ++ro root-cause-resource* resource
    |    |    |    |    |    |    | {root-cause-analysis}? 
    |    |    |    |    |    |    | ++ro time-created  yang:date-and-time
    |    |    |    |    |    |    ++ro is-cleared  boolean
++-ro last-raised     yang:date-and-time
++-ro last-changed    yang:date-and-time
++-ro perceived-severity severity
++-ro alarm-text      alarm-text
++-ro status-change*  [time] {alarm-history}?
   ++-ro time         yang:date-and-time
   ++-ro perceived-severity severity-with-clear
   ++-ro alarm-text   alarm-text
++-ro operator-state-change*  [time] {operator-actions}?

Every alarm has three important states, the resource clearance state "is-cleared", the severity "perceived-severity" and the operator state available in the operator state change list.

In order to see the alarm history the resource state changes are available in the "status-change" list and the operator history is available in the "operator-state-change" list.

4.5. The Shelved Alarms List

The shelved alarm list has the same structure as the alarm list above. It shows all the alarms that matches the shelving criteria (/alarms/control/alarm-shelving).

4.6. Alarm Profiles

Alarm profiles (/alarms/alarm-profile) is a list of configurable alarm types. The list supports configurable alarm severity levels in the container "alarm-severity-assignment-profile". If an alarm matches the configured alarm type it MUST use the configured severity level(s) instead of the system default. This configuration MUST also be represented in the alarm inventory.

```yaml
+-rw alarm-profile*
  [alarm-type-id alarm-type-qualifier-match resource]
    (alarm-profile)?
  +-rw alarm-type-id          alarm-type-id
  +-rw alarm-type-qualifier-match  string
  +-rw resource                resource-match
  +-rw description             string
  +--rw alarm-severity-assignment-profile
     {severity-assignment}?
     +-rw severity-levels*     severity
```
4.7. Operations

The alarm module supports the following actions to manage the alarms:

/alarms/alarm-list/purge-alarms: Delete alarms from the "alarm-list" according to specific criteria, for example all cleared alarms older than a specific date.

/alarms/alarm-list/compress-alarms: Compress the "status-change" list for the alarms.

/alarms/alarm-list/alarm/set-operator-state: Change the operator state for an alarm. For example, an alarm can be acknowledged by setting the operator state to "ack".

/alarms/shelved-alarm-list/purge-shelved-alarms: Delete alarms from the "shelved-alarm-list" according to specific criteria, for example all alarms older than a specific date.

/alarms/shelved-alarm-list/compress-shelved-alarms: Compress the "status-change" list for the alarms.

4.8. Notifications

The alarm module supports a general notification to report alarm state changes. It carries all relevant parameters for the alarm management application.

There is also a notification to report that an operator changed the operator state on an alarm, like acknowledge.

If the alarm inventory is changed, for example a new card type is inserted, a notification will tell the management application that new alarm types are available.

5. Relationship to the ietf-hardware YANG module

RFC 8348 [RFC8348] defines the "ietf-hardware" YANG data model for the management of hardware. The "alarm-state" in RFC 8348 is a summary of the alarm severity levels that may be active on the specific hardware component. It does not say anything about how alarms are reported, and it doesn’t provide any details of the alarms.

The mapping between the alarm YANG data model and the "alarm-state" in RFC 8348 is as follows:
resource: Corresponds to an entry in the list "/hardware/component/"

is-cleared: No bit set in "/hardware/component/state/alarm-state"

perceived-severity: Corresponding bit set in "/hardware/component/state/alarm-state".

operator-state-change/state: If the alarm is acknowledged by the operator, the bit "under-repair" is in "/hardware/component/state/alarm-state".

6. Alarm YANG Module

This YANG module references [RFC6991] and [XSD-TYPES].

  description "This module defines an interface for managing alarms. Main inputs to the module design are the 3GPP Alarm IRP, ITU-T X.733 and ANSI/ISA-18.2 alarm standards."

  Main features of this module include:
* Alarm list:
  A list of all alarms. Cleared alarms stay in the list until explicitly purged.

* Operator actions on alarms:
  Acknowledging and closing alarms.

* Administrative actions on alarms:
  Purging alarms from the list according to specific criteria.

* Alarm inventory:
  A management application can read all alarm types implemented by the system.

* Alarm shelving:
  Shelving (blocking) alarms according to specific criteria.

* Alarm profiles:
  A management system can attach further information to alarm types, for example overriding system default severity levels.

This module uses a stateful view on alarms. An alarm is a state for a specific resource (note that an alarm is not a notification). An alarm type is a possible alarm state for a resource. For example, the tuple:

('link-alarm', 'GigabitEthernet0/25')

is an alarm of type ‘link-alarm’ on the resource ‘GigabitEthernet0/25’.

Alarm types are identified using YANG identities and an optional string-based qualifier. The string-based qualifier allows for dynamic extension of the statically defined alarm types. Alarm types identify a possible alarm state and not the individual notifications. For example, the traditional ‘link-down’ and ‘link-up’ notifications are two notifications referring to the same alarm type ‘link-alarm’.

With this design there is no ambiguity about how alarm and alarm clear correlation should be performed: notifications that report the same resource and alarm type are considered updates of the same alarm, e.g., clearing an active alarm or changing the severity of an alarm.
The instrumentation can update 'severity' and 'alarm-text' on an existing alarm. The above alarm example can therefore look like:

```yang
(('link-alarm', 'GigabitEthernet0/25'),
  warning,
  'interface down while interface admin state is up')
```

There is a clear separation between updates on the alarm from the underlying resource, like clear, and updates from an operator like acknowledge or closing an alarm:

```yang
(('link-alarm', 'GigabitEthernet0/25'),
  warning,
  'interface down while interface admin state is up',
  cleared,
  closed)
```

Administrative actions like removing closed alarms older than a given time is supported.

This alarm module does not define how the underlying instrumentation detects and clears the specific alarms. That belongs to the SDO or enterprise that owns that specific technology.

}

/*
 * Identities
 */

identity alarm-type-id {
  description
    "Base identity for alarm types. A unique identification of the alarm, not including the resource. Different resources can share alarm types. If the resource reports the same alarm type, it is to be considered to be the same alarm. The alarm type is a simplification of the different X.733 and 3GPP alarm IRP alarm correlation mechanisms and it allows for hierarchical extensions.

    A string-based qualifier can be used in addition to the identity in order to have different alarm types based on information not known at design-time, such as values in textual SNMP Notification var-binds."
Standards and vendors can define sub-identities to clearly identify specific alarm types.

This identity is abstract and MUST NOT be used for alarms.

/*
  * Common types
  */

typedef resource {
  type union {
    type instance-identifier {
      require-instance false;
    }
    type yang:object-identifier;
    type string;
    type yang:uuid;
  }
  description
  "This is an identification of the alarming resource, such as an interface. It should be as fine-grained as possible both to guide the operator and to guarantee uniqueness of the alarms.

  If the alarming resource is modeled in YANG, this type will be an instance-identifier.

  If the resource is an SNMP object, the type will be an object-identifier.

  If the resource is anything else, for example a distinguished name or a CIM path, this type will be a string.

  If the alarming object is identified by a UUID use the uuid type. Be cautious when using this type, since a UUID is hard to use for an operator.

  If the server supports several models, the precedence should be in the order as given in the union definition.";
}

typedef resource-match {
  type union {
    type yang:xpath1.0;
    type yang:object-identifier;
    type string;
  }
  description
"This type is used to match resources of type ‘resource’. Since the type ‘resource’ is a union of different types, the ‘resource-match’ type is also a union of corresponding types.

If the type is given as an XPath 1.0 expression, a resource of type ‘instance-identifier’ matches if the instance is part of the node set that is the result of evaluating the XPath 1.0 expression. For example, the XPath 1.0 expression:

```
/ietf-interfaces:interfaces/ietf-interfaces:interface
   [ietf-interfaces:type='ianaiift:ethernetCsmacd']
```

would match the resource instance-identifier:

```
/if:interfaces/if:interface[if:name='eth1'],
```

assuming that the interface ‘eth1’ is of type ‘ianaiift:ethernetCsmacd’.

If the type is given as an object identifier, a resource of type ‘object-identifier’ matches if the match object identifier is a prefix of the resource’s object identifier. For example, the value:

```
1.3.6.1.2.1.2.2
```

would match the resource object identifier:

```
1.3.6.1.2.1.2.2.1.1.5
```

If the type is given as an UUID or a string, it is interpreted as an XML Schema regular expression, which matches a resource of type ‘yang:uuid’ or ‘string’ if the given regular expression matches the resource string.

If the type is given as an XPath expression it is evaluated in the following XPath context:

- The set of namespace declarations is the set of prefix and namespace pairs for all YANG modules implemented by the server, where the prefix is the YANG module name and the namespace is as defined by the ‘namespace’ statement in the YANG module.

  If a leaf of this type is encoded in XML, all namespace declarations in scope on the leaf element are added to the set of namespace declarations. If a prefix found in the XML is already present in the set of namespace declarations.
declarations, the namespace in the XML is used.
   
o The set of variable bindings is empty.

   o The function library is the core function library and the functions defined in Section 10 of RFC 7950.

   o The context node is the root node in the data tree."

<CODE ENDS>

7. X.733 Extensions

Many alarm systems are based on the X.733, [X.733], and X.736 [X.736] alarm standards. This module augments the alarm inventory, the alarm lists and the alarm notification with X.733 and X.736 parameters.

The module also supports a feature whereby the alarm manager can configure the mapping from alarm types to X.733 "event-type" and "probable-cause" parameters. This might be needed when the default mapping provided by the system is in conflict with other management systems or not considered correct.

Note that the IETF Alarm Module term "resource" is synonymous to the ITU term "managed object".

8. The X.733 Mapping Module

This YANG module references [X.721], [X.733] and [X.736].

  "WG Web:  <http://tools.ietf.org/wg/ccamp>  
  WG List:  <mailto:ccamp@ietf.org>  

    Editor:  Stefan Vallin"
description
"This module augments the ietf-alarms module with X.733 alarm parameters.

The following structures are augmented with X.733 event type and probable cause:

1) alarms/alarm-inventory: all possible alarm types
2) alarms/alarm-list: every alarm in the system
3) alarm-notification: notifications indicating alarm state changes
4) alarms/shelved-alarms

The module also optionally allows the alarm management system to configure the mapping from the IETF Alarm module alarm keys to the ITU tuple (event-type, probable-cause).

The mapping does not include a corresponding X.733 specific problem value. The recommendation is to use the ‘alarm-type-qualifier’ leaf which serves the same purpose.

The module uses an integer and a corresponding string for probable cause instead of a globally defined enumeration, in order to be able to manage conflicting enumeration definitions. A single globally defined enumeration is challenging to maintain.

9. IANA Considerations

This document registers two URIs in the IETF XML registry [RFC3688]. Following the format in RFC 3688, the following registrations are requested to be made.

Registrant Contact: The IESG.
XML: N/A, the requested URI is an XML namespace.

Registrant Contact: The IESG.
XML: N/A, the requested URI is an XML namespace.

This document registers two YANG modules in the YANG Module Names registry [RFC6020].

name:        ietf-alarms
prefix:      al
reference:   RFC XXXX

name:        ietf-alarms-x733
prefix:      x733
reference:   RFC XXXX

10. Security Considerations

The YANG module specified in this document defines a schema for data that is designed to be accessed via network management protocols such as NETCONF [RFC6241] or RESTCONF [RFC8040]. The lowest NETCONF layer is the secure transport layer, and the mandatory-to-implement secure transport is Secure Shell (SSH) [RFC6242]. The lowest RESTCONF layer is HTTPS, and the mandatory-to-implement secure transport is TLS [RFC8446].

The Network Configuration Access Control model (NACM) [RFC8341] provides the means to restrict access for particular NETCONF or RESTCONF users to a preconfigured subset of all available NETCONF or RESTCONF protocol operations and content.
The list of alarms itself may be potentially sensitive from a security perspective, in that it potentially gives an attacker an authoritative picture of the (broken) state of the network.

There are a number of data nodes defined in this YANG module that are writable/creatable/deletable (i.e., config true, which is the default). These data nodes may be considered sensitive or vulnerable in some network environments. Write operations (e.g., edit-config) to these data nodes without proper protection can have a negative effect on network operations. These are the subtrees and data nodes and their sensitivity/vulnerability:

/alarms/control/notify-status-changes: This leaf controls whether an alarm should notify based on various state changes. Unauthorized access to this leaf could have a negative impact on operational procedures relying on fine-grained alarm state change reporting.

/alarms/control/alarm-shelving/shelf: This list controls the shelving (blocking) of alarms. Unauthorized access to this list could jeopardize the alarm management procedures since these alarms will not be notified and not be part of the alarm list.

/alarms/control/alarm-profile/alarm-severity-assignment-profile: This list controls the severity levels of an alarm. Unauthorized access to this could for example downgrade the severity of an alarm and thereby have a negative impact on the alarm monitoring process.

Some of the operations in this YANG module may be considered sensitive or vulnerable in some network environments. It is thus important to control access to these operations. These are the operations and their sensitivity/vulnerability:

/alarms/alarm-list/purge-alarms: This action deletes alarms from the alarm list. Unauthorized use of this action could jeopardize the alarm management procedures since the deleted alarms may be vital for the alarm management application.

/alarms/alarm-list/alarm/set-operator-state: This action can be used by the operator to indicate the level of human intervention on an alarm. Unauthorized use of this action could result in alarms being ignored by operators.

11. Acknowledgements

The authors wish to thank Viktor Leijon and Johan Nordlander for their valuable input on forming the alarm model.
The authors also wish to thank Nick Hancock, Joey Boyd, Tom Petch and Balazs Lengyel for their extensive reviews and contributions to this document.

Appendix A. Vendor-specific Alarm Types Example

This example shows how to define alarm types in a vendor-specific module. In this case the vendor "xyz" has chosen to define top level identities according to X.733 event types.
module example-xyz-alarms {
    namespace "urn:example:xyz-alarms";
    prefix xyz-al;

    import ietf-alarms {
        prefix al;
    }

    identity xyz-alarms {
        base al:alarm-type-id;
    }

    identity communications-alarm {
        base xyz-alarms;
    }

    identity quality-of-service-alarm {
        base xyz-alarms;
    }

    identity processing-error-alarm {
        base xyz-alarms;
    }

    identity equipment-alarm {
        base xyz-alarms;
    }

    identity environmental-alarm {
        base xyz-alarms;
    }

    // communications alarms
    identity link-alarm {
        base communications-alarm;
    }

    // QoS alarms
    identity high-jitter-alarm {
        base quality-of-service-alarm;
    }

    // Appendix B. Alarm Inventory Example

    This shows an alarm inventory, it shows one alarm type defined only
    with the identifier, and another dynamically configured. In the
    latter case a digital input has been connected to a smoke-detector,
    therefore the "alarm-type-qualifier" is set to "smoke-detector" and
    the "alarm-type-id" to "environmental-alarm".

Appendix C. Alarm List Example

In this example we show an alarm that has toggled [major, clear, major]. An operator has acknowledged the alarm.

```xml
<alarms xmlns="urn:ietf:params:xml:ns:yang:ietf-alarms"
  xmlns:xyz-al="urn:example:xyz-alarms"
  xmlns:dev="urn:example:device">
  <alarm-list>
    <number-of-alarms>1</number-of-alarms>
    <last-changed>2018-04-08T08:39:50.00Z</last-changed>
    <alarm>
      <resource/>
      <alarm-type-id>xyz-al:link-alarm</alarm-type-id>
      <is-cleared>false</is-cleared>
      <time-created>2018-04-08T08:20:10.00Z</time-created>
      <alt-resource>1.3.6.1.2.1.2.2.1.17</alt-resource>
      <last-raised>2018-04-08T08:39:40.00Z</last-raised>
    </alarm>
  </alarm-list>
</alarms>
```
Appendix D. Alarm Shelving Example

This example shows how to shelf alarms. We shelf alarms related to the smoke-detectors since they are being installed and tested. We also shelf all alarms from FastEthernet1/0.
<alarms xmlns="urn:ietf:params:xml:ns:yang:ietf-alarms"
    xmlns:xyz-al="urn:example:xyz-alarms"
    xmlns:dev="urn:example:device">
    <control>
        <alarm-shelving>
            <shelf>
                <name>FE10</name>
                <resource>
                    /dev/interfaces/dev:interface[name='FastEthernet1/0']
                </resource>
            </shelf>
            <shelf>
                <name>detectortest</name>
                <alarm-type>
                    <alarm-type-id>
                        xyz-al:environmental-alarm
                    </alarm-type-id>
                    <alarm-type-qualifier-match>
                        smoke-alarm
                    </alarm-type-qualifier-match>
                    <alarm-type/>
                </alarm-type>
            </shelf>
        </alarm-shelving>
    </control>
</alarms>

Appendix E.  X.733 Mapping Example

This example shows how to map a dynamic alarm type (alarm-type-id=environmental-alarm, alarm-type-qualifier=smoke-alarm) to the corresponding X.733 "event-type" and "probable-cause" parameters.

<alarms xmlns="urn:ietf:params:xml:ns:yang:ietf-alarms"
    xmlns:xyz-al="urn:example:xyz-alarms">
    <control>
        <x733-mapping
            xmlns="urn:ietf:params:xml:ns:yang:ietf-alarms-x733">
            <alarm-type-id>xyz-al:environmental-alarm</alarm-type-id>
            <alarm-type-qualifier-match>
                smoke-alarm
            </alarm-type-qualifier-match>
            <event-type>quality-of-service-alarm</event-type>
            <probable-cause>777</probable-cause>
        </x733-mapping>
    </control>
</alarms>
Appendix F. Relationship to other alarm standards

This section briefly describes how this alarm module relates to other relevant standards.

F.1. Alarm definition

The table below summarizes relevant definitions of the term "alarm" in other alarm standards.

<table>
<thead>
<tr>
<th>Standard</th>
<th>Definition</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>X.733</td>
<td>error: A deviation of a system from normal operation. fault: The physical or algorithmic cause of a malfunction. Faults manifest themselves as errors. alarm: A notification, of the form defined by this function, of a specific event. An alarm may or may not represent an error.</td>
<td>The X.733 alarm definition is focused on the notification as such and not the state. X.733 defines an alarm as a deviation from normal condition, but without the requirement that it needs corrective actions.</td>
</tr>
<tr>
<td>G.7710</td>
<td>Alarms are indications that are automatically generated by a device as a result of the declaration of a failure.</td>
<td>The G.7710 definition is close to the original X.733 definition.</td>
</tr>
<tr>
<td>Alarm MIB [RFC3877]</td>
<td>Alarm: Persistent indication of a fault. Fault: Lasting error or warning condition. Error: A deviation of a system from normal operation.</td>
<td>RFC 3877 defines the term alarm referring back to &quot;a deviation from normal operation&quot;. The Alarm YANG model adds the requirement that it should require a corrective action and should be undesired, not only a deviation from normal. The alarm MIB is state oriented in the same way as the Alarm YANG, it focuses on the &quot;lasting condition&quot;,</td>
</tr>
<tr>
<td>Standard</td>
<td>Definition</td>
<td></td>
</tr>
<tr>
<td>----------</td>
<td>------------</td>
<td></td>
</tr>
<tr>
<td>ISA [ISA182]</td>
<td>Alarm: An audible and/or visible means of indicating to the operator an equipment malfunction, process deviation or abnormal condition requiring a response. The ISA standard adds an important requirement to the &quot;deviation from normal condition state&quot;: requiring a response.</td>
<td></td>
</tr>
<tr>
<td>EEMUA [EEMUA]</td>
<td>An alarm is an event to which an operator must knowingly react, respond, and acknowledge - not simply acknowledge and ignore. This is the foundation for the definition of alarm in this document. It focuses on the core criteria that an action is really needed.</td>
<td></td>
</tr>
<tr>
<td>3GPP Alarm IRP [ALARMIRP]</td>
<td>3GPP v15: An alarm signifies an undesired condition of a resource (e.g. device, link) for which an operator action is required. It emphasizes a key requirement that operators [...] should not be informed about an undesired condition unless it requires operator action. 3GPP v12: alarm: abnormal network entity condition, which categorizes an event as a fault. fault: a deviation of a system from normal operation, which may result in the loss of operational capabilities [...] The latest 3GPP Alarm IRP version uses literally the same alarm definition as this alarm module. It is worth noting that earlier versions used a definition not requiring an operator action and the more broad definition of deviation from normal condition. The earlier version also defined an alarm as a special case of &quot;event&quot;.</td>
<td></td>
</tr>
</tbody>

Table 1: Definition of alarm in standards

The evolution of the definition of alarm moves from focused on events reporting a deviation from normal operation towards a definition to a undesired "state" which "requires an operator action".
F.2. Data model

This section describes how this YANG alarm module relates to other standard data models. Note well that we cover other data models for alarm interfaces. Not other standards such as SDO specific alarms for example.

F.2.1. X.733

X.733 has acted as a base for several alarm data models over the year. The YANG alarm module differs in the following ways:

X.733 models the alarm list as a list of notifications. The YANG alarm module defines the alarm list as the current alarm states for the resources, which is generated from the state change reporting notifications.

In X.733 an alarm can have the severity level clear. In the YANG alarm module "clear" is not a severity level, it is a separate state of the alarm. An alarm can have the following states for example (major, cleared), (minor, not cleared)

X.733 uses a flat globally defined enumerated "probable-cause" to identify alarm types. This alarm module uses a hierarchical YANG identity, "alarm-type". This enables delegation of alarm types within organizations. It also lets management reason about abstract alarm types corresponding to base identities, see Section 3.2.

The YANG alarm module has not included the majority of the X.733 alarm attributes. Rather these are defined in an augmenting module if "strict" X.733 compliance is needed.

F.2.2. RFC 3877, the Alarm MIB

The MIB in RFC 3877 takes a different approach, rather than defining a concrete data model for alarms, it defines a model to map existing SNMP managed objects and notifications into alarm states and alarm notifications. This was necessary since MIBs were already defined with both managed objects and notifications indicating alarms, for example linkUp and linkDown notifications in combination with ifAdminState and ifOperState. So RFC 3877 can not really be compared to the alarm YANG module in that sense.

The Alarm MIB maps existing MIB definitions into alarms, alarmModelTable. The upside of that is that a SNMP Manager can at runtime read the possible alarm types. This corresponds to the alarmInventory in the alarm YANG module.
F.2.3. 3GPP Alarm IRP

The 3GPP Alarm IRP is an evolution of X.733. Main differences between the alarm YANG module and 3GPP are:

3GPP keeps the majority of the X.733 attributes, the alarm YANG module does not.

3GPP introduced overlapping and possibly conflicting keys for alarms, alarmId and (managed object, event type, probable cause, specific problem). (See Annex C in [X.733] Example 3). In the YANG alarm module the key for identifying an alarm instance is clearly defined by ("resource", "alarm-type-id", "alarm-type-qualifier"). See also Section 3.4 for more information.

The alarm YANG module clearly separates the resource/instrumentation life cycle from the operator life cycle. 3GPP allows operators to set the alarm severity to clear, this is not allowed by this module, rather an operator closes an alarm which does not affect the severity.

F.2.4. G.7710

G.7710 is different than the previous referenced alarm standards. It does not define a data model for alarm reporting. It defines common equipment management function requirements including alarm instrumentation. The scope is transport networks.

The requirements in G.7710 corresponds to features in the alarm YANG module in the following way:

Alarm Severity Assignment Profile (ASAP): the alarm profile "/alarms/alarm-profile/".

Alarm Reporting Control (ARC): alarm shelving "/alarms/control/alarm-shelving/" and the ability to control alarm notifications "/alarms/control/notify-status-changes". Alarm shelving corresponds to the use case of turning off alarm reporting for a specific resource, the NALM state in M.3100.

Appendix G. Alarm Usability Requirements

This section defines usability requirements for alarms. Alarm usability is important for an alarm interface. A data model will help in defining the format but if the actual alarms are of low value we have not gained the goal of alarm management.
Common alarm problems and the cause of the problems are summarized in Table 2. This summary is adopted to networking based on the ISA [ISA182] and EEMUA [EEMUA] standards.
<table>
<thead>
<tr>
<th>Problem</th>
<th>Cause</th>
<th>How this module address the cause</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alarms are generated but they are ignored by the operator.</td>
<td>&quot;Nuisance&quot; alarms (chattering alarms and fleeting alarms), faulty hardware, redundant alarms, cascading alarms, incorrect alarm settings, alarms have not been rationalized, the alarms represent log information rather than true alarms.</td>
<td>Strict definition of alarms requiring corrective response. Alarm requirements in Table 3.</td>
</tr>
<tr>
<td>When alarms occur, operators do not know how to respond.</td>
<td>Insufficient alarm response procedures and not well defined alarm types.</td>
<td>The alarm inventory lists all alarm types and corrective actions. Alarm requirements in Table 3.</td>
</tr>
<tr>
<td>The alarm display is full of alarms, even when there is nothing wrong.</td>
<td>Nuisance alarms, stale alarms, alarms from equipment not in service.</td>
<td>The alarm definition and alarm shelving.</td>
</tr>
<tr>
<td>During a failure, operators are flooded with so many alarms that they do not know which ones are the most important.</td>
<td>Incorrect prioritization of alarms. Not using advanced alarm techniques (e.g. state-based alarming).</td>
<td>State-based alarm model, alarm rate requirements in Table 4 and Table 5</td>
</tr>
</tbody>
</table>

Table 2: Alarm Problems and Causes

Based upon the above problems EEMUA gives the following definition of a good alarm:
<table>
<thead>
<tr>
<th>Characteristic</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Relevant</td>
<td>Not spurious or of low operational value.</td>
</tr>
<tr>
<td>Unique</td>
<td>Not duplicating another alarm.</td>
</tr>
<tr>
<td>Timely</td>
<td>Not long before any response is needed or too late to do anything.</td>
</tr>
<tr>
<td>Prioritized</td>
<td>Indicating the importance that the operator deals with the problem.</td>
</tr>
<tr>
<td>Understandable</td>
<td>Having a message which is clear and easy to understand.</td>
</tr>
<tr>
<td>Diagnostic</td>
<td>Identifying the problem that has occurred.</td>
</tr>
<tr>
<td>Advisory</td>
<td>Indicative of the action to be taken.</td>
</tr>
<tr>
<td>Focusing</td>
<td>Drawing attention to the most important issues.</td>
</tr>
</tbody>
</table>

Table 3: Definition of a Good Alarm

Vendors SHOULD rationalize all alarms according to above. Another crucial requirement is acceptable alarm notification rates. Vendors SHOULD make sure that they do not exceed the recommendations from EEMUA below:

<table>
<thead>
<tr>
<th>Long Term Alarm Rate in Steady Operation</th>
<th>Acceptability</th>
</tr>
</thead>
<tbody>
<tr>
<td>More than one per minute</td>
<td>Very likely to be unacceptable.</td>
</tr>
<tr>
<td>One per 2 minutes</td>
<td>Likely to be over-demanding.</td>
</tr>
<tr>
<td>One per 5 minutes</td>
<td>Manageable.</td>
</tr>
<tr>
<td>Less than one per 10 minutes</td>
<td>Very likely to be acceptable.</td>
</tr>
</tbody>
</table>

Table 4: Acceptable Alarm Rates, Steady State
<table>
<thead>
<tr>
<th>Number of alarms displayed in 10 minutes following a major network problem</th>
<th>Acceptability</th>
</tr>
</thead>
<tbody>
<tr>
<td>More than 100</td>
<td>Definitely excessive and very likely to lead to the operator to abandon the use of the alarm system.</td>
</tr>
<tr>
<td>20-100</td>
<td>Hard to cope with.</td>
</tr>
<tr>
<td>Under 10</td>
<td>Should be manageable - but may be difficult if several of the alarms require a complex operator response.</td>
</tr>
</tbody>
</table>

Table 5: Acceptable Alarm Rates, Burst

The numbers in Table 4 and Table 5 are the sum of all alarms for a network being managed from one alarm console. So every individual system or NMS contributes to these numbers.

Vendors SHOULD make sure that the following rules are used in designing the alarm interface:

1. Rationalize the alarms in the system to ensure that every alarm is necessary, has a purpose, and follows the cardinal rule - that it requires an operator response. Adheres to the rules of Table 3

2. Audit the quality of the alarms. Talk with the operators about how well the alarm information support them. Do they know what to do in the event of an alarm? Are they able to quickly diagnose the problem and determine the corrective action? Does the alarm text adhere to the requirements in Table 3?

3. Analyze and benchmark the performance of the system and compare it to the recommended metrics in Table 4 and Table 5. Start by identifying nuisance alarms, standing alarms at normal state and startup.
