A YANG Data Model for Fabric Topology in Data Center Networks
draft-ietf-i2rs-yang-dc-fabric-network-topology-12

Abstract

This document defines a YANG data model for fabric topology in Data Center Networks and it represents one possible view of the data center fabric. This document focuses on the data model only and does not endorse any kind of network design that could be based on the abovementioned model.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at https://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on May 25, 2019.

1. Introduction

A data center (DC) network can be composed of single or multiple fabrics which are also known as PODs (Points Of Delivery). These fabrics may be heterogeneous due to implementation of different technologies when a DC network is upgraded or new techniques and features are rolled out. For example, Fabric A may use VXLAN while Fabric B may use VLAN within a DC network. Likewise, an existing fabric may use VXLAN while a new fabric, for example a fabric introduced for DC upgrade and expansion, may implement a technique discussed in NVO3 WG, such as Geneve [I-D. draft-ietf-nvo3-geneve]. The configuration and management of such DC networks with heterogeneous fabrics could result in considerable complexity.

For a DC network, a fabric can be considered as an atomic structure for management purposes. From this point of view, the management of the DC network can be decomposed into a set of tasks to manage each fabric separately, as well as the fabric interconnections. The advantage of this method is to make the overall management tasks flexible and easy to extend in the future.
As a basis for DC fabric management, this document defines a YANG data model [RFC6020][RFC7950] for a possible view of the fabric-based data center topology. To do so, it augments the generic network and network topology data models defined in [RFC8345] with information that is specific to data center fabric networks.

The model defines the generic configuration and operational state for a fabric-based network topology, which can subsequently be extended by vendors with vendor-specific information as needed. The model can be used by a network controller to represent its view of the fabric topology that it controls and expose this view to network administrators or applications for DC network management.

Within the context of topology architecture defined in [RFC8345], this model can also be treated as an application of the I2RS network topology model [RFC8345] in the scenario of data center network management. It can also act as a service topology when mapping network elements at the fabric layer to elements of other topologies, such as L3 topologies as defined in [RFC8346].

By using the fabric topology model defined in this document, people can treat a fabric as a holistic entity and focus on characteristics of a fabric (such as encapsulation type, gateway type,) as well as its connections to other fabrics while putting the underlay topology aside. As such, clients can consume the topology information at the fabric level with no need to be aware of the entire set of links and nodes in the corresponding underlay networks. A fabric topology can be configured by a network administrator using the controller by adding physical devices and links into a fabric. Alternatively, fabric topology can be learned from the underlay network infrastructure.

2. Definitions and Acronyms

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [RFC2119] [RFC8174] when, and only when, they appear in all capitals, as shown here.

2.1. Terminology

POD: a module of network, compute, storage, and application components that work together to deliver networking services. It represents a repeatable design pattern. Its components maximize the modularity, scalability, and manageability of data centers.

Fabric: composed of several PODs to form a data center network.
3. Model Overview

This section provides an overview of the data center fabric topology model and its relationship with other topology models.

3.1. Topology Model structure

The relationship of the DC fabric topology model and other topology models is shown in the following figure.

```
+------------------------+
|      network model     |
+------------------------+

+------------------------+------------------------+
| network topology model |
+------------------------+

+------------------------+------------------------+------------------------+------------------------+
|   L1   |   L2   |   L3   | Fabric |
| topology | topology | topology | topology |
| model     | model     | model     | model     |
```

Figure 1: The network data model structure

From the perspective of resource management and service provisioning for a data center network, the fabric topology model augments the basic network topology model with definitions and features specific to a DC fabric, to provide common configuration and operations for heterogeneous fabrics.

3.2. Fabric Topology Model

The fabric topology model module is designed to be generic and can be applied to data center fabrics built with different technologies, such as VLAN, VXLAN. The main purpose of this module is to configure and manage fabrics and their connections. It provides a fabric-based topology view for data center applications.

3.2.1. Fabric Topology

In the fabric topology module, a fabric is modeled as a node of a network, as such the fabric-based data center network consists of a set of fabric nodes and their connections. The following depicts a
snippet of the definitions to show the main structure of the model. The notation syntax follows [RFC8340].

module: ietf-dc-fabric-topology
augment /nw:networks/nw:network/nw:network-types:
  +--rw fabric-network!

augment /nw:networks/nw:network/nw:node:
  +--rw fabric-attributes
    +--rw fabric-id?  fabric-id
    +--rw name?      string
    +--rw type?      fabrictype:underlay-network-type
    +--rw description?  string
    +--rw options
    +--...

augment /nw:networks/nw:network/nw:node/nt:termination-point:
  +--ro fport-attributes
    +--ro name?      string
    +--ro role?      fabric-port-role
    +--ro type?      fabric-port-type

The fabric topology module augments the generic ietf-network and ietf-network-topology modules as follows:

o A new topology type "ietf-dc-fabric-topology" is defined and added under the "network-types" container of the ietf-network module.

o Fabric is defined as a node under the network/node container. A new container "fabric-attributes" is defined to carry attributes for a fabric such as gateway mode, fabric types, involved device nodes, and links.

o Termination points (in network topology module) are augmented with fabric port attributes defined in a container. The "termination-point" here is used to represent a fabric "port" that provides connections to other nodes, such as an internal device, another fabric externally, or end hosts.

Details of the fabric node and the fabric termination point extension will be explained in the following sections.

3.2.2. Fabric node extension

As an atomic network (that is a set of nodes and links which composes a POD and also supports a single overlay/underlay instance), a fabric itself is composed of a set of network elements i.e. devices, and related links. The configuration of a fabric is contained under the
"fabric-attributes" container depicted as follows. The notation syntax follows [RFC8340].

```plaintext
+--rw fabric-attributes
   +--rw name? string
   +--rw type? fabrictype:underlay-network-type
   +--rw vni-capacity
      |   +--rw min? int32
      |   +--rw max? int32
   +--rw description? string
   +--rw options
      |   +--rw gateway-mode? enumeration
      |   +--rw traffic-behavior? enumeration
      |   +--rw capability-supported* fabrictype:service-capabilities
   +--rw device-nodes* [device-ref]
      |   +--rw device-ref fabrictype:node-ref
      |   +--rw role*? fabrictype:device-role
   +--rw device-links* [link-ref]
      |   +--rw link-ref fabrictype:link-ref
   +--rw device-ports* [port-ref]
      +--rw port-ref fabrictype:tp-ref
      +--rw port-type? fabrictypes:port-type
      +--rw bandwidth? fabrictypes:bandwidth
```

In the module, additional data objects for fabric nodes are introduced by augmenting the "node" list of the network module. New objects include fabric name, type of the fabric, descriptions of the fabric as well as a set of options defined in a "options" container. The "options" container includes the gateway-mode type (centralized or distributed) and traffic-behavior (whether an Access Control Lists (ACLs) is needed for the traffic). Also, it includes a list of device-nodes and related links as supporting-nodes to form a fabric network. These device nodes and links are represented as leaf-refs of existing nodes and links in the underlay topology. For the device-node, the "role" object is defined to represent the role of a device within the fabric, such as "SPINE" or "LEAF", which should work together with the gateway-mode.

3.2.3. Fabric termination-point extension

Since a fabric can be considered as a node, "termination-points" can represent fabric "ports" that connect to other fabrics, end hosts, as well as devices inside the fabric.
As such, the set of "termination-points" of a fabric indicate all connections of the fabric, including its internal connections, interconnections with other fabrics, and connections to end hosts.

The structure of fabric ports is as follows. The notation syntax follows [RFC8340].

The structure of fabric ports is as follows:

```
  augment /nw:networks/nw:network/nw:node/nt:termination-point:
    +--ro fport-attributes
    |   +--ro name?    string
    |   +--ro role?    fabric-port-role
    |   +--ro type?    fabric-port-type
    |   +--ro device-port? tp-ref
    |   +--ro (tunnel-option)?
```

It augments the termination points (in network topology module) with fabric port attributes defined in a container.

New nodes are defined for fabric ports including fabric name, role of the port within the fabric (internal port, external port to outside network, access port to end hosts), port type (L2 interface, L3 interface). By defining the device-port as a tp-ref, a fabric port can be mapped to a device node in the underlay network.

Also, a new container for tunnel-options is introduced to present the tunnel configuration on a port.

The termination point information is learned from the underlay networks, not configured by the fabric topology layer.

4. Fabric YANG Module

This module imports typedefs from [RFC8345], and it references [RFC7348] and [RFC8344].

```
<CODE BEGINS> file "ietf-dc-fabric-types@2018-11-08.yang"
module ietf-dc-fabric-types {
  yang-version 1.1;
  prefix fabric-types;

  import ietf-network {
    prefix nw;
  }

<CODE ENDS>
```
This module contains a collection of YANG definitions for Fabric.

This document registers the following YANG modules in the "YANG Module Names" registry (RFC6020):

NOTE TO THE RFC EDITOR: In the list below, please replace references to "draft-ietf-i2rs-yang-dc-fabric-network-topology-12 (RFC form)" with RFC number when published (i.e. RFC xxxx).

Name: ietf-dc-fabric-types
Prefix: fabrictypes

Name: ietf-dc-fabric-topology
Prefix: fabric

Name: ietf-dc-fabric-topology-state
Prefix: sfabric

6. Security Considerations

The YANG module defined in this document is designed to be accessed via network management protocols such as NETCONF [RFC6241] or RESTCONF [RFC8040]. The lowest NETCONF layer is the secure transport layer, and the mandatory-to-implement secure transport is Secure Shell (SSH) [RFC6242]. The lowest RESTCONF layer is HTTPS, and the mandatory-to-implement secure transport is TLS [RFC5246].

The NETCONF access control model [RFC8341] provides the means to restrict access for particular NETCONF or RESTCONF users to a preconfigured subset of all available NETCONF or RESTCONF protocol
operations and content. The subtrees and data nodes and their sensitivity/vulnerability in the ietf-dc-fabric-topology module are as follows:

fabric-attributes: A malicious client could attempt to sabotage the configuration of important fabric attributes, such as device-nodes or type.

Some of the readable data nodes in this YANG module may be considered sensitive or vulnerable in some network environments. It is thus important to control read access (e.g., via get, get-config, or notification) to these data nodes. The subtrees and data nodes and their sensitivity/vulnerability in the ietf-dc-fabric-topology module are as follows:

fport-attributes: A malicious client could attempt to read the connections of fabrics without permission, such as device-port, name.

7. Acknowledgements

We wish to acknowledge the helpful contributions, comments, and suggestions that were received from Alexander Clemm, Donald E. Eastlake, Xufeng Liu, Susan Hares, Wei Song, Luis M. Contreras and Benoit Claise.

Appendix A. Non NMDA -state modules

The YANG module ietf-dc-fabric-topology defined in this document augments two modules, ietf-network and ietf-network-topology, that are designed to be used in conjunction with implementations that support the Network Management Datastore Architecture (NMDA) defined in [RFC8342]. In order to allow implementations to use the model even in case when NMDA is not supported, a set of companion modules have been defined that represent a state model of networks and network topologies, ietf-network-state and ietf-network-topology-state, respectively.

In order to be able to use the model for fabric topologies defined in this in this document in conjunction with non-NMDA compliant implementations, a corresponding companion module needs to be introduced as well. This companion module, ietf-dc-fabric-topology-state, mirrors ietf-dc-fabric-topology. However, the module augments ietf-network-state (instead of ietf-network and ietf-network-topology) and all of its data nodes are non-configurable.

Like ietf-network-state and ietf-network-topology-state, ietf-dc-fabric-topology-state SHOULD NOT be supported by implementations that support NMDA. It is for this reason that the module is defined in the Appendix.

The definition of the module follows below. As the structure of the module mirrors that of its underlying module, the YANG tree is not depicted separately.

description
"This module contains a collection of YANG definitions for
Fabric state, representing topology that is either learned,
or topology that results from applying topology that has been
configured per the ietf-dc-fabric-topology model, mirroring
the corresponding data nodes in this model.

This model mirrors the configuration tree of ietf-dc-fabric-
topology, but contains only read-only state data. The model
is not needed when the implementation infrastructure supports
the Network Management Datastore Architecture (NMDA).
