Two-Way Active Measurement Protocol (TWAMP) Data Model
draft-ietf-ippm-twamp-yang-08

Abstract

This document specifies a data model for client and server implementations of the Two-Way Active Measurement Protocol (TWAMP). We define the TWAMP data model through Unified Modeling Language (UML) class diagrams and formally specify it using YANG.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at https://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on October 16, 2018.

1. Introduction

The Two-Way Active Measurement Protocol (TWAMP) [RFC5357] is used to measure network performance parameters such as latency, bandwidth, and packet loss by sending probe packets and measuring their experience in the network. To date, TWAMP implementations do not come with a standard management framework, and, as such, implementors have no choice except to provide a proprietary mechanism. This document addresses this gap by formally specifying the TWAMP data model using YANG [RFC7950].

1.1. Motivation

In current TWAMP deployments the lack of a standardized data model limits the flexibility to dynamically instantiate TWAMP-based measurements across equipment from different vendors. In large, virtualized, and dynamically instantiated infrastructures where network functions are placed according to orchestration algorithms as discussed in Unifying Carrier and Cloud Networks: Problem Statement and Challenges [I-D.unify-nfvrg-challenges]DevOps For Software-Defined Telecom Infrastructures [I-D.unify-nfvrg-devops], proprietary mechanisms for managing TWAMP measurements pose severe limitations with respect to programmability.

Two major trends call for standardizing TWAMP management aspects. First, we expect that in the coming years large-scale and multi-vendor TWAMP deployments will become the norm. From an operations perspective, using several vendor-specific TWAMP configuration mechanisms when one standard mechanism could provide an alternative is expensive and inefficient. Second, the increasingly software-defined and virtualized nature of network infrastructures, based on dynamic service chains [NSC] and programmable control and management planes Software-Defined Networking (SDN): Layers and Architecture Terminology [RFC7426] requires a well-defined data model for TWAMP implementations. This document defines such a TWAMP data model and specifies it formally using the YANG [RFC7950] data modeling language.

Note to RFC Editor:

Please replace the date 2018-04-16 in Section 5.2 of the draft with the date of publication of this draft as a RFC. Also, replace reference to RFC XXXX, and draft-ietf-port-twamp-test with the RFC numbers assigned to the drafts.
1.2. Terminology

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", 
"SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and 
"OPTIONAL" in this document are to be interpreted as described in BCP 
14 [RFC2119] [RFC8174] when, and only when, they appear in all 
capitals, as shown here.

1.3. Document Organization

The rest of this document is organized as follows. Section 2 
presents the scope and applicability of this document. Section 3 
provides a high-level overview of the TWAMP data model. Section 4 
details the configuration parameters of the data model and Section 5 
specifies in YANG the TWAMP data model. Section 6 lists illustrative 
examples which conform to the YANG data model specified in this 
document. Appendix A elaborates these examples further.

2. Scope, Model, and Applicability

The purpose of this document is the specification of a vendor- 
independent data model for TWAMP implementations.

Figure 1 illustrates a redrawn version of the TWAMP logical model 
found in Section 1.2 of TWAMP [RFC5357]. The figure is annotated 
with pointers to the UML diagrams provided in this document and 
associated with the data model of the four logical entities in a 
TWAMP deployment, namely the TWAMP Control-Client, Server, Session- 
Sender and Session-Reflector.

As per TWAMP [RFC5357], unlabeled links in Figure 1 are left 
unspecified and may be proprietary protocols.

```
[Fig. 3] +----------------+                          +--------+
| Control-Client |  <-- TWAMP-Control -->   | Server |
+----------------+                          +--------+
   ^                                        ^
   V                                        V
[Fig. 5] +----------------+                     +-------------------+
| Session-Sender |  <-- TWAMP-Test --> | Session-Reflector |
+----------------+                     +-------------------+
[Fig. 5] [Fig. 6]
```

Figure 1: Annotated TWAMP logical model
As per TWAMP [RFC5357], a TWAMP implementation may follow a simplified logical model, in which the same node acts both as Control-Client and Session-Sender, while another node acts at the same time as TWAMP Server and Session-Reflector. Figure 2 illustrates this simplified logical model and indicates the interaction between the TWAMP configuration client and server using, for instance, NETCONF [RFC6241] or RESTCONF [RFC8040].

The data model defined in this document is orthogonal to the specific protocol used between the Config client and Config server to communicate the TWAMP configuration parameters.

Operational actions such as how TWAMP-Test sessions are started and stopped, how performance measurement results are retrieved, or how stored results are cleared, and so on, are not addressed by the configuration model defined in this document. As noted above, such operational actions are not part of the TWAMP specification TWAMP [RFC5357] and hence are out of scope of this document. See also Appendix B.

3. Data Model Overview

The TWAMP data model includes four categories of configuration items.

First, global configuration items relate to parameters that are set on a per device level. For example, the administrative status of the device with respect to whether it allows TWAMP sessions and, if so, in what capacity (e.g. Control-Client, Server or both), is a typical instance of a global configuration item.
A second category includes attributes that can be configured on a per TWAMP-Control connection basis, such as the Server IP address.

A third category includes attributes related to per TWAMP-Test session attributes, for instance setting different values in the Differentiated Services Code Point (DSCP) field.

Finally, the data model includes attributes that relate to the operational state of the TWAMP implementation.

As we describe the TWAMP data model in the remaining sections of this document, readers should keep in mind the functional entity grouping illustrated in Figure 1.

3.1. Control-Client

A TWAMP Control-Client has an administrative status field set at the device level that indicates whether the node is enabled to function as such.

Each TWAMP Control-Client is associated with zero or more TWAMP-Control connections. The main configuration parameters of each control connection are:

- A name which can be used to uniquely identify at the Control-Client a particular control connection. This name is necessary for programmability reasons because at the time of creation of a TWAMP-Control connection not all IP and TCP port number information needed to uniquely identify the connection is available.

- The IP address of the interface the Control-Client will use for connections.

- The IP address of the remote TWAMP Server.

- Authentication and encryption attributes such as KeyID, Token and the Client Initialization Vector (Client-IV); see also the last paragraph of Section 6 in OWAMP [RFC4656] and Randomness Requirements for Security [RFC4086].

Each TWAMP-Control connection, in turn, is associated with zero or more TWAMP-Test sessions. For each test session we note the following configuration items:

- The test session name that uniquely identifies a particular test session at the Control-Client and Session-Sender. Similarly to the control connections above, this unique test session name is
needed because at the time of creation of a TWAMP-Test session, for example, the source UDP port number is not known to uniquely identify the test session.

- The IP address and UDP port number of the Session-Sender on the path under test by TWAMP.
- The IP address and UDP port number of the Session-Reflector on said path.
- Information pertaining to the test packet stream, such as the test starting time, which performance metric is to be used Registry for Performance Metrics [I-D.ietf-ippm-metric-registry], or whether the test should be repeated.

### 3.2. Server

Each TWAMP Server has an administrative status field set at the device level to indicate whether the node is enabled to function as a TWAMP Server.

Each Server is associated with zero or more TWAMP-Control connections. Each control connection is uniquely identified by the 4-tuple {Control-Client IP address, Control-Client TCP port number, Server IP address, Server TCP port}. Control connection configuration items on a TWAMP Server are read-only.

### 3.3. Session-Sender

A TWAMP Session-Sender has an administrative status field set at the device level that indicates whether the node is enabled to function as such.

There is one Session-Sender instance for each TWAMP-Test session that is initiated from the sending device. Primary configuration fields include:

- The test session name that MUST be identical with the corresponding test session name on the TWAMP Control-Client (Section 3.1).
- The control connection name, which along with the test session name uniquely identify the TWAMP Session-Sender instance.
- Information pertaining to the test packet stream, such as, for example, the number of test packets and the packet distribution to be employed; see also Network performance measurement with periodic streams [RFC3432].
3.4. Session-Reflector

Each TWAMP Session-Reflector has an administrative status field set at the device level to indicate whether the node is enabled to function as such.

Each Session-Reflector is associated with zero or more TWAMP-Test sessions. For each test session, the REFWAIT timeout parameter which determines whether to discontinue the session if no packets have been received (TWAMP [RFC5357], Section 4.2) can be configured.

Read-only access to other data model parameters, such as the Sender IP address is foreseen. Each test session can be uniquely identified by the 4-tuple mentioned in Section 3.2.

4. Data Model Parameters

This section defines the TWAMP data model using UML and introduces selected parameters associated with the four TWAMP logical entities. The complete TWAMP data model specification is provided in the YANG module presented in Section 5.2.

4.1. Control-Client

The client container (see Figure 3) holds items that are related to the configuration of the TWAMP Control-Client logical entity (recall Figure 1).

The client container includes an administrative configuration parameter (client/admin-state) that indicates whether the device is allowed to initiate TWAMP-Control connections.
The client container holds a list (mode-preference-chain) which specifies the Mode values according to their preferred order of use by the operator of this Control-Client, including the authentication and encryption Modes. Specifically, mode-preference-chain lists the mode and its corresponding priority, expressed as a 16-bit unsigned integer, where zero is the highest priority and subsequent values are monotonically increasing.
Depending on the Modes available in the Server Greeting, the Control-Client MUST choose the highest priority Mode from the configured mode-preference-chain list.

Note that the list of preferred Modes may set bit position combinations when necessary, such as when referring to the extended TWAMP features in Mixed Security Mode for TWAMP [RFC5618], Individual Session Control Feature for TWAMP [RFC5938], TWAMP Reflect Octets and Symmetrical Size Features [RFC6038], and IKEv2-Derived Shared Secret Key for OWAMP and TWAMP [RFC7717]. If the Control-Client cannot determine an acceptable Mode, it MUST respond with zero Mode bits set in the Set-up Response message, indicating it will not continue with the control connection.

In addition, the client container holds a list named key-chain which relates KeyIDs with the respective secret keys. Both the Server and the Control-Client use the same mappings from KeyIDs to shared secrets (key-id and secret-key in Figure 3, respectively). The Server, being prepared to conduct sessions with more than one Control-Client, uses KeyIDs to choose the appropriate secret-key; a Control-Client would typically have different secret keys for different Servers. The secret-key is the shared secret, an octet string of arbitrary length whose interpretation as a text string is unspecified. The key-id and secret-key encoding SHOULD follow Section 9.4 of YANG [RFC7950]. The derived key length (dkLen in PKCS #5: Password-Based Cryptography Specification Version 2.1 [RFC8018]) MUST be 16 octets for the AES Session-key used for encryption and 32 octets for the HMAC-SHA1 Session-key used for authentication; see also Section 6.10 of OWAMP [RFC4656].

Each client container also holds a list of control connections, where each item in the list describes a TWAMP control connection initiated by this Control-Client. There SHALL be one ctrl-connection per TWAMP-Control (TCP) connection that is to be initiated from this device.

In turn, each ctrl-connection holds a list of test-session-request. test-session-request holds information associated with the Control-Client for this test session. This includes information associated with the Request-TW-Session/Accept-Session message exchange (see Section 3.5 of TWAMP [RFC5357]).

There SHALL be one instance of test-session-request for each TWAMP-Test session that is to be negotiated by this TWAMP-Control connection via a Request-TW-Session/Accept-Session exchange.
The Control-Client is also responsible for scheduling TWAMP-Test sessions so test-session-request holds information related to these actions (e.g. pm-index, repeat-interval).

4.2. Server

The server container (see Figure 4) holds items that are related to the configuration of the TWAMP Server logical entity (recall Figure 1).

The server container includes an administrative configuration parameter (server/admin-state) that indicates whether the device is allowed to receive TWAMP-Control connections.

A device operating in the Server role cannot configure attributes on a per TWAMP-Control connection basis, as it has no foreknowledge of the incoming TWAMP-Control connections to be received. Consequently, any parameter that the Server might want to apply to an incoming control connection must be configured at the overall Server level and applied to all incoming TWAMP-Control connections.
Each server container holds a list named key-chain which relates KeyIDs with the respective secret keys. As mentioned in Section 4.1, both the Server and the Control-Client use the same mappings from KeyIDs to shared secrets. The Server, being prepared to conduct sessions with more than one Control-Client, uses KeyIDs to choose the appropriate secret-key; a Control-Client would typically have different secret keys for different Servers. key-id tells the Server which shared-secret the Control-Client wishes to use for authentication or encryption.

Each incoming control connection active on the Server is represented by a ctrl-connection. There SHALL be one ctrl-connection per incoming TWAMP-Control (TCP) connection that is received and active on the Server. Each ctrl-connection can be uniquely identified by the 4-tuple {client-ip, client-tcp-port, server-ip, server-tcp-port}. All items in the ctrl-connection list are read-only.
4.3. Session-Sender

The session-sender container, illustrated in Figure 5, holds items that are related to the configuration of the TWAMP Session-Sender logical entity.

The session-sender container includes an administrative parameter (session-sender/admin-state) that controls whether the device is allowed to initiate TWAMP-Test sessions.

```
+----------------+  0..* +---------------------------+
| session-sender |<>-----| test-session              |
+----------------+       +---------------------------+
          | name                      |
          | ctrl-connection-name {ro} |
          | fill-mode                 |
          | number-of-packets         |
          | state {ro}                |
          | sent-packets       {ro}   |
          | rcv-packets         {ro}   |
          | last-sent-seq        {ro}  |
          | last-rcv-seq         {ro}  |
+---------------------------+  ^
              ^
                V
              | 1
              |------------------+
              | packet-distribution|
              |------------------+
              | periodic / poisson|
              |------------------+
              |                  |
              | periodic-interval|
              |------------------+
              |                  |
              | lambda           |
              | max-interval     |
              |------------------+
```

Figure 5: TWAMP Session-Sender UML class diagram

Each TWAMP-Test session initiated by the Session-Sender will be represented by an instance of a test-session object. There SHALL be
one instance of test-session for each TWAMP-Test session for which packets are being sent.

4.4. Session-Reflector

The session-reflector container, illustrated in Figure 6, holds items that are related to the configuration of the TWAMP Session-Reflector logical entity.

The session-reflector container includes an administrative parameter (session-reflector/admin-state) that controls whether the device is allowed to respond to incoming TWAMP-Test sessions.

A device operating in the Session-Reflector role cannot configure attributes on a per-session basis, as it has no foreknowledge of what incoming sessions it will receive. As such, any parameter that the Session-Reflector might want to apply to an incoming TWAMP-Test session must be configured at the overall Session-Reflector level and are applied to all incoming sessions.
Each incoming TWAMP-Test session that is active on the Session-Reflector SHALL be represented by an instance of a test-session object. All items in the test-session object are read-only.

Instances of test-session are indexed by a session identifier (sid). This value is auto-allocated by the TWAMP Server as test session requests are received, and communicated back to the Control-Client in the SID field of the Accept-Session message; see Section 4.3 of TWAMP Reflect Octets and Symmetrical Size Features [RFC6038].

When attempting to retrieve operational data for active test sessions from a Session-Reflector device, the user will not know what sessions are currently active on that device, or what SIDs have been auto-allocated for these test sessions. If the user has network access to the Control-Client device, then it is possible to read the data for this session under client/ctrl-connection/test-session-request/sid and obtain the SID (see Figure 3). The user may then use this SID
value as an index to retrieve an individual session-reflector/test-
session instance on the Session-Reflector device.

If the user has no network access to the Control-Client device, then
the only option is to retrieve all test-session instances from the
Session-Reflector device, and then pick out specific test-session
instances of interest to the user. This could be problematic if a
large number of test sessions are currently active on that device.

Each Session-Reflector TWAMP-Test session contains the following
4-tuple: (parent-connection-client-ip, parent-connection-client-tcp-
port, parent-connection-server-ip, parent-connection-server-tcp-
port). This 4-tuple MUST correspond to the equivalent 4-tuple
(client-ip, client-tcp-port, server-ip, server-tcp-port) in server/
ctrl-connection. This 4-tuple allows the user to trace back from the
TWAMP-Test session to the (parent) TWAMP-Control connection that
negotiated this test session.

5. Data Model

This section formally specifies the TWAMP data model using YANG.

5.1. YANG Tree Diagram

This section presents a simplified graphical representation of the
TWAMP data model using a YANG tree diagram. Readers should keep in
mind that the limit of 72 characters per line forces us to introduce
artificial line breaks in some tree diagram nodes. Tree diagrams
used in this document follow the notation defined in YANG Tree
Diagrams [RFC8340].

```yang
module: ietf-twamp

  description
    "This YANG module specifies a vendor-independent data model for the Two-Way Active Measurement Protocol (TWAMP)."
The data model covers four TWAMP logical entities, namely, Control-Client, Server, Session-Sender, and Session-Reflector, as illustrated in the annotated TWAMP logical model (Fig. 1 of RFC XXXX).

This YANG module uses features to indicate which of the four logical entities are supported by a TWAMP implementation.

}
grouping count {
    leaf count {
        type uint8 {
            range "10..31";
        }
        default 10;
        description
            "Parameter communicated to the Control-Client as part of
            the Server Greeting message and used for deriving a key
            from a shared secret as per Section 3.1 of RFC 4656:
            MUST be a power of 2 and at least 1024. It is configured
            by providing said power. For example, configuring 15 here
            means count 2^15 = 32768. The default is 10,
            meaning 2^10 = 1024.";
    }
    description
        "Reusable data structure for count, which is used both in the
        Server and the Control-Client.";
}

grouping max-count-exponent {
    leaf max-count {
        type uint8 {
            range 10..31;
        }
        default 15;
        description
            "This parameter limits the maximum Count value, which MUST
            be a power of 2 and at least 1024 as per RFC 5357. It is
            configured by providing said power. For example,
            configuring 10 here means max count 2^10 = 1024.
            The default is 15, meaning 2^15 = 32768.

            A TWAMP Server uses this configured value in the
            Server-Greeting message sent to the Control-Client.

            A TWAMP Control-Client uses this configured value to
            prevent denial-of-service (DOS) attacks by closing the
            control connection to the Server if it ‘receives a
            Server-Greeting message with Count greater that its
            maximum configured value’, as per Section 6 of RFC 5357.

            Further, note that according to Section 6 of RFC 5357:";
'If an attacking system sets the maximum value in Count (2**32), then the system under attack would stall for a significant period of time while it attempts to generate keys.

TWAMP-compliant systems SHOULD have a configuration control to limit the maximum count value. The default max-count value SHOULD be 32768.'

RFC 5357 does not qualify 'significant period' in terms of time, but it is clear that this depends on the processing capacity available and operators need to pay attention to this security consideration.

6. Data Model Examples

This section presents a simple but complete example of configuring all four entities in Figure 1, based on the YANG module specified in Section 5. The example is illustrative in nature, but aims to be self-contained, i.e. were it to be executed in a real TWAMP implementation it would lead to a correctly configured test session. For completeness, examples are provided for both IPv4 and IPv6.

A more elaborated example, which also includes authentication parameters, is provided in Appendix A.

6.1. Control-Client

Figure 8 shows a configuration example for a Control-Client with client/admin-state enabled. In a real implementation following Figure 2 this would permit the initiation of TWAMP-Control connections and TWAMP-Test sessions.

[NOTE: ‘\’ line wrapping is for formatting only]

```xml
<?xml version="1.0" encoding="utf-8"?>
<config xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <twamp xmlns="urn:ietf:params:xml:ns:yang:ietf-twamp">
    <client>
      <admin-state>true</admin-state>
    </client>
  </twamp>
</config>
```

Figure 8: XML instance enabling Control-Client operation.

The following example shows a Control-Client with two instances of client/ctrl-connection, one called "RouterA" and another called "RouterB". Each TWAMP-Control connection is to a different Server. The control connection named "RouterA" has two test session requests. The TWAMP-Control connection named "RouterB" has no TWAMP-Test session requests.

[NOTE: ‘\’ line wrapping is for formatting only]

```xml
<?xml version="1.0" encoding="utf-8"?>
<config xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <twamp xmlns="urn:ietf:params:xml:ns:yang:ietf-twamp">
    <client>
      <admin-state>true</admin-state>
    </client>
    <client>
    </client>
    <client>
    </client>
  </twamp>
</config>
```
<admin-state>true</admin-state>
<ctrl-connection>
  <name>RouterA</name>
  <client-ip>203.0.113.1</client-ip>
  <server-ip>203.0.113.2</server-ip>
  <test-session-request>
    <name>Test1</name>
    <sender-ip>203.0.113.3</sender-ip>
    <sender-udp-port>54001</sender-udp-port>
    <reflector-ip>203.0.113.4</reflector-ip>
    <reflector-udp-port>50001</reflector-udp-port>
    <start-time>0</start-time>
  </test-session-request>
  <test-session-request>
    <name>Test2</name>
    <sender-ip>203.0.113.1</sender-ip>
    <sender-udp-port>54001</sender-udp-port>
    <reflector-ip>203.0.113.2</reflector-ip>
    <reflector-udp-port>50001</reflector-udp-port>
    <start-time>0</start-time>
  </test-session-request>
</ctrl-connection>
<ctrl-connection>
  <name>RouterB</name>
  <client-ip>203.0.113.1</client-ip>
  <server-ip>203.0.113.3</server-ip>
</ctrl-connection>
</client>
</twamp>
</config>

[Note: '\' line wrapping is for formatting only]
6.2. Server

Figure 9 shows a configuration example for a Server with server/admin-state enabled, which permits a device following Figure 2 to respond to TWAMP-Control connections and TWAMP-Test sessions.

[note: ‘\’ line wrapping is for formatting only]

```xml
<?xml version="1.0" encoding="utf-8"?>
<config xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <twamp xmlns="urn:ietf:params:xml:ns:yang:ietf-twamp">
    <server>
      <admin-state>true</admin-state>
    </server>
  </twamp>
</config>
```

Figure 9: XML instance enabling Server operation.

The following example presents a Server with the TWAMP-Control connection corresponding to the control connection name (client/ctrl-connection/name) "RouterA" presented in Section 6.1.
6.3. Session-Sender

Figure 10 shows a configuration example for a Session-Sender with session-sender/admin-state enabled, which permits a device following Figure 2 to initiate TWAMP-Test sessions.
Figure 10: XML instance enabling Session-Sender operation.

The following configuration example shows a Session-Sender with the two TWAMP-Test sessions presented in Section 6.1.

6.4. Session-Reflector

This configuration example shows a Session-Reflector with session-reflector/admin-state enabled, which permits a device following Figure 2 to respond to TWAMP-Test sessions.
Figure 11: XML instance enabling Session-Reflector operation.

The following example shows the two Session-Reflector TWAMP-Test sessions corresponding to the test sessions presented in Section 6.3.

```xml
<?xml version="1.0" encoding="utf-8"?>
<data xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">

7. Security Considerations

The YANG module specified in Section 5 this document defines a schema for data that is designed to be accessed via network management protocols such as NETCONF [RFC6241] or RESTCONF [RFC8040]. The lowest NETCONF [RFC6241] layer is the secure transport layer, and the mandatory-to-implement secure transport is Secure Shell (SSH) [RFC6242]. The lowest RESTCONF layer is HTTPS, and the mandatory-to-implement secure transport is TLS [RFC5246].

The NETCONF Access Control Module (NACM) [RFC8341] provides the means to restrict access for particular NETCONF or RESTCONF users to a preconfigured subset of all available NETCONF or RESTCONF protocol operations and content..

There are a number of nodes defined in this YANG module which are writeable. These data nodes may be considered sensitive and vulnerable to attacks in some network environments. Ability to write into these nodes without proper protection can have a negative effect on the devices that support this feature.

Examples of nodes that are particularly vulnerable include several timeout values put in the protocol to protect against sessions that are not active but are consuming resources.
8. IANA Considerations

This document registers a URI in the IETF XML registry [RFC3688]. Following the format in IETF XML Registry [RFC3688], the following registration is requested to be made.

Registrant Contact: The IPPM WG of the IETF.

XML: N/A, the requested URI is an XML namespace.

This document registers a YANG module in the YANG Module Names registry YANG [RFC6020].

name: ietf-twamp

prefix: twamp

reference: RFC XXXX

9. Acknowledgements

We thank Fred Baker, Kevin D’Souza, Gregory Mirsky, Brian Trammell, Robert Sherman, and Marius Georgescu for their thorough and constructive reviews, comments and text suggestions.

Haoxing Shen contributed to the definition of the YANG module in Section 5.

Jan Lindblad and Ladislav Lhokta did thorough reviews of the YANG module and the examples in Appendix A.

Appendix B. TWAMP Operational Commands

TWAMP operational commands could be performed programmatically or manually, e.g. using a command-line interface (CLI).

With respect to programmability, YANG can be used to define NETCONF Remote Procedure Calls (RPC), therefore it would be, in principle, possible to define TWAMP RPC operations for actions such as starting or stopping control connections or test sessions or groups of sessions; retrieving results; clearing stored results, and so on.

However, TWAMP [RFC5357] does not attempt to describe such operational actions. Refer also to Section 2 and the unlabeled links in Figure 1. In actual deployments different TWAMP implementations may support different sets of operational commands, with different restrictions. Therefore, this document considers it the responsibility of the individual implementation to define its corresponding TWAMP operational commands data model.
