Abstract

A Mobile IPv6 node requires a Home Agent address, a home address, and IPsec security associations with its Home Agent before it can start utilizing Mobile IPv6 service. RFC 3775 requires that some or all of these are statically configured. This document defines how a Mobile IPv6 node can bootstrap this information from non-
topological information and security credentials preconfigured on the Mobile Node. The solution defined in this document solves the bootstrapping problem from draft-ietf-mip6-bootstrapping-ps-02 when the Mobile Node’s mobility service is authorized by a different service provider than basic network access, and is therefore generically applicable to any bootstrapping case.

1. Introduction

Mobile IPv6 [2] requires the Mobile Node to know its Home Agent Address, its own Home Address and the cryptographic materials (e.g. shared keys or certificates) needed to set up IPsec security associations with the Home Agent in order to protect Mobile IPv6 signaling. This is generally referred to as the Mobile IPv6 bootstrapping problem [4].

Mobile IPv6 base protocol does not specify any method to automatically acquire this information, which means that network administrators are normally required to manually set configuration data on Mobile Nodes and HAs. However, in real deployments, manual configuration does not scale as the Mobile Nodes increase in number.

As discussed in [4], several bootstrapping scenarios can be identified depending on the relationship between the network operator that authenticates a mobile node for granting network access service (Access Service Authorizer, ASA) and the service provider that authorizes Mobile IPv6 service (Mobility Service Authorizer, MSA). This document describes a solution to the bootstrapping problem that is applicable in a scenario where the MSA and the ASA are different entities (i.e. split scenario).
2. Terminology

General mobility terminology can be found in [10]. The following additional terms are used here:

ASA
Access Service Authorizer. A network operator that authenticates a mobile node and establishes the mobile node’s authorization to receive Internet service.

ASP
Access Service Provider. A network operator that provides direct IP packet forwarding to and from the end host.

MSA
Mobility Service Authorizer. A service provider that authorizes Mobile IPv6 service.

MSP
Mobility Service Provider. A service provider that provides Mobile IPv6 service. In order to obtain such service, the mobile node must be authenticated and prove authorization to obtain the service.

Split scenario
A scenario where mobility service and network access service are authorized by different entities. This implies that MSA is different from ASA.
### 3. Split scenario

In the problem statement description [4] there is a clear assumption that mobility service and network access service can be separate. This assumption implies that mobility service and network access service may be authorized by different entities. As an example, the service model defined in [4] allows an enterprise network to deploy a Home Agent and offer Mobile IPv6 service to a user, even if the user is accessing the Internet independent of its enterprise account (e.g., by using his personal WiFi hotspot account at a coffee shop).

Therefore, in this document it is assumed that network access and mobility service are authorized by different entities, which means that authentication and authorization for mobility service and network access will be considered separately. This scenario is called split scenario.

Moreover, the model defined in [4] separates the entity providing the service from the entity that authenticates and authorizes the user. This is similar to the roaming model for network access. Therefore, in the split scenario, two different cases can be identified depending on the relationship between the entity that provides the mobility service (i.e. Mobility Service Provider, MSP) and the entity that authenticates and authorizes the user (i.e. Mobility Service Authorizer, MSA).

Figure 1 depicts the split scenario when the MSP and the MSA are the same entity. This means that the network operator that provides the Home Agent authenticates and authorizes the user for mobility service.

---

![Figure 1 - Split Scenario (MSA == MSP)](image)

Figure 2 shows the split scenario in case the MSA and the MSP are two different entities. This might happen if the Mobile Node is...
far from its MSA network and is assigned a closer HA to optimize performance or if the MSA cannot provide any Home Agent and relies on a third party (i.e. the MSP) to grant mobility service to its users. Notice that the MSP might be or might not also be the network operator that is providing network access (i.e. ASP, Access Service Provider).

![Diagram](image)

Figure 2 - Split Scenario (MSA != MSP)

Note that Figure 1 and Figure 2 assume the use of an AAA protocol to authenticate and authorize the Mobile Node for mobility service. However, since IKEv2 allows EAP client authentication only and the server authentication needs to be performed based on certificates or public keys, the Mobile Node potentially requires a certificate revocation list check (CTL check) even though an AAA protocol is used to authenticate and authorize the Mobile Node for mobility service.

If, instead, a PKI is used, the Mobile Node and HA exchange certificates and there is no AAA server involved [23]. This is conceptually similar to Figure 1, since the MSP == MSA, except the Home Agent, and potentially the Mobile Node, may require a certificate revocation list check (CRL check) with the Certificate Authority (CA). The CA may be either internal or external to the MSP. Figure 3 illustrates.
The split scenario is the simplest model that can be identified, since no assumptions about the access network are made. This implies that the mobility service is bootstrapped independently from the authentication protocol for network access used (e.g. PANA, EAP). For this reason, the solution described in this document and developed for this scenario could also be applied to the integrated access network deployment model [4], even if it might not be optimized.
4. Components of the solution

The bootstrapping problem is composed of different sub-problems that can be solved independently in a modular way. The components identified and a brief overview of their solution follow.

- **HA address discovery.** The Mobile Node needs to discover the address of its Home Agent. The main objective of a bootstrapping solution is to minimize the data pre-configured on the Mobile Node. For this reason, the DHAAD defined in [2] may not be applicable in real deployments since it is required that the Mobile Node is pre-configured with the home network prefix and it does not allow an operator to load balance by having Mobile Nodes dynamically assigned to Home Agents located in different subnets. This document defines a solution for Home Agent address discovery that is based on Domain Name Service (DNS), introducing a new DNS SRV record [5]. The unique information that needs to be pre-configured on the Mobile Node is the domain name of the MSP.

- **IPsec Security Associations setup.** Mobile IPv6 requires that a Mobile Node and its Home Agent share an IPsec SA in order to protect binding updates and other Mobile IPv6 signaling. This document provides a solution that is based on IKEv2 and follows what is specified in [6]. The IKEv2 peer authentication can be performed both using certificates and using EAP, depending on the network operator’s deployment model.

- **Home Address (HoA) assignment.** The Mobile Node needs to know its Home Address in order to bootstrap Mobile IPv6 operation. The Home Address is assigned by the Home Agent during the IKEv2 exchange (as described in [6]). The solution defined in this document also allows the Mobile Node to auto-configure its Home Address based on stateless auto-configuration ([22]), Cryptographically Generated Addresses ([11]) or privacy addresses ([12]).

- **Authentication and Authorization with MSA.** The user must be authenticated in order for the MSP to grant the service. Since the user credentials can be verified only by the MSA, this authorization step is performed by the MSA. Moreover, the mobility service must be explicitly authorized by the MSA based on the user’s profile. These operations are performed in different ways depending on the credentials used by the Mobile Node during the IKEv2 peer authentication and on the backend infrastructure (PKI or AAA).

An optional part of bootstrapping involves providing a way for the Mobile Node to have its FQDN updated in the DNS with a dynamically assigned home address. While not all applications will require this service, many networking applications use the FQDN to obtain
an address for a node prior to starting IP traffic with it. The solution defined in this document specifies that the dynamic DNS update is performed by the Home Agent or through the AAA infrastructure, depending on the trust relationship in place.
5. Protocol Operations

This section describes in detail the procedures needed to perform Mobile IPv6 bootstrapping based on the components identified in the previous section.

5.1. Home Agent Address Discovery

Once a Mobile Node has obtained network access, it can perform Mobile IPv6 bootstrapping. For this purpose, the Mobile Node queries the DNS server to request information on Home Agent service. As mentioned before in the document, the only information that needs to be pre-configured on the Mobile Node is the domain name of the Mobility Service Provider.

The Mobile Node needs to obtain the IP address of the DNS server before it can send a DNS request. This can be pre-configured on the Mobile Node or obtained through DHCPv6 from the visited link [13]. In any case, it is assumed that there is some kind of mechanism by which the Mobile Node is configured with a DNS server since a DNS server is needed for many other reasons.

Two options for DNS lookup for a Home Agent address are identified in this document: DNS lookup by Home Agent Name and DNS lookup by service name.

This document does not provide a specific mechanism to load balance different Mobile Nodes among Home Agents. It is possible for an MSP to achieve coarse-grained load balancing by dynamically updating the SRV RR priorities to reflect the current load on the MSP’s collection of Home Agents. Mobile Nodes then use the priority mechanism to preferentially select the least loaded HA. The effectiveness of this technique depends on how much of a load it will place on the DNS servers, particularly if dynamic DNS is used for frequent updates.

While this document specifies a Home Agent Address Discovery solution based on DNS, when the ASP and the MSP are the same entity DHCP may be used. See [17] for details.

5.1.1. DNS lookup by Home Agent Name

In this case, the Mobile Node is configured with the Fully Qualified Domain Name of the Home Agent. As an example, the Mobile Node could be configured with the name "ha1.example.com", where "example.com" is the domain name of the MSP granting the mobility service.

The Mobile Node constructs a DNS request, by setting the QNAME to the name of the Home Agent. The request has QTYPE set to ‘AAAA’, so that the DNS server sends the IPv6 address of the Home Agent.
Once the DNS server replies to this query, the Mobile Node knows its Home Agent address and can run IKEv2 in order to set up the IPsec SAs and get a Home Address.

Additionally, the ability to provide a mobile node with a localized home agent (e.g. on the visited link) can help to optimize handover signaling and improve routing efficiency in bidirectional tunneling mode. There are a variety of ways this can be achieved in an interoperable way. One way is to provision the mobile node with an FQDN for a local home agent when it configures for the local link. Another way is to specify an interoperable naming convention for constructing home agent FQDNs based on location. For example, an operator might assign the FQDN "ha.locationA.operator.com" to the Home Agent located in "location A" and the FQDN "ha.locationB.operator.com" to the Home Agent located in "location B". If the Mobile Node wants to use a Home Agent located in "location A", it will set the QNAME to "ha.locationA.operator.com" in the DNS request. The exact way in which localized Home Agents are configured is out of scope for this draft.

5.1.2. DNS lookup by service name

RFC 2782 [5] defines the service resource record (SRV RR) that allows an operator to use several servers for a single domain, to move services from host to host, and to designate some hosts as primary servers for a service and others as backups. Clients ask for a specific service/protocol for a specific domain and get back the names of any available servers.

RFC 2782 [5] also describes the policies to choose a service agent based on the preference and weight values. The DNS SRV record may contain the preference and weight values for multiple Home Agents available to the Mobile Node in addition to the Home Agent FQDNs. If multiple Home Agents are available in the DNS SRV record then Mobile Node is responsible for processing the information as per policy and for picking one Home Agent. If the Home Agent of choice does not respond for some reason or the IKEv2 authentication fails, the Mobile Node SHOULD try other Home Agents on the list.

The service name for Mobile IPv6 Home Agent service as required by RFC 2782 is "mip6" and the protocol name is "ipv6". Note that a transport name cannot be used here because Mobile IPv6 does not run over a transport protocol.

The SRV RR has a DNS type code of 33. As an example, the Mobile constructs a request with QNAME set to "_mip6._ipv6.example.com" and QTYPE to SRV. The reply contains the FQDNs of one or more servers, that can then be resolved in a separate DNS transaction to the IP addresses. However, if there is room in the SRV reply, it is RECOMMENDED that the DNS server also return the IP addresses...
of the Home Agents in AAAA records as part of the additional data section (in order to avoid requiring an additional DNS round trip to resolve the FQDNs).

5.1.3. Anycast Address for Home Agent Assignment

A FQDN MAY be bound to an IPv6 anycast address rather than to a unicast address for a Home Agent. Since anycast addresses are indistinguishable from unicast addresses, there is no distinction in the AAAA record between a unicast address and an anycast address. The anycast address allows the home network to assign a Home Agent to a Mobile Node on a case by case basis at the time that the Mobile Node bootstraps, rather than having the Mobile Node select the Home Agent address. Section 5.2.1. below describes how the IKEv2 transaction is modified by anycast Home Agent assignment. A FQDN bound to an anycast address MAY be returned by a SRV RR query. Mobile Nodes that implement this specification MUST be prepared to handle an anycast address for Home Agent assignment.

The anycast address reserved by RFC 2526 [8] for Home Agents on the same link MAY be used for bootstrapping. Other deployment-specific anycast addresses, spanning a wider topology, MAY also be used.

Note that anycast forwarding as specified in RFC 4291 [9] allows the node which has the anycast address assigned to one of its network interfaces to make the decision about to which address forwarding should occur based only on routing metric information. Use of any other criteria, such as load balancing or service profile offered by the Home Agent, in a standardized way is currently unsupported. Assignment based on other criteria than routing metrics can be achieved by having the home agent receiving the forwarded message perform the home agent selection based on other criteria, but the mechanism for this is out of scope of this draft.

5.2. IPsec Security Associations setup

As soon as the Mobile Node has discovered the Home Agent Address, it establishes an IPsec Security Association with the Home Agent itself through IKEv2. The detailed description of this procedure is provided in [6]. If the Mobile Node wants the HA to register the Home Address in the DNS, it MUST use the FQDN as the initiator identity in IKE_AUTH step of the IKEv2 exchange (IDi). This is needed because the Mobile Node has to provide it is the owner of the FQDN provided in the subsequent DNS Update Option. See section 6 and section 9 for a more detailed analysis on this issue.
The IKEv2 Mobile Node to Home Agent authentication can be performed using either IKEv2 public key signatures or the Extensible Authentication Protocol (EAP). The details about how to use IKEv2 authentication are described in [6] and [7]. Choice of an IKEv2 peer authentication method depends on the deployment. However, IKEv2 restricts the Home Agent to Mobile Node authentication to use public key signature-based authentication.

5.2.1. IKEv2 Transaction With Anycast Home Agent Assignment

If an anycast address is returned in response to DNS resolution of an FQDN, the IKEv2 transaction between the Mobile Node and Home Agent is slightly modified. The Mobile Node sends the IKE_SA_INIT request to the anycast address. The node which has the anycast address assigned to one of its network interfaces selects a Home Agent address from the set of Home Agents managed by the node, and forwards the IKE_SA_INIT. If the set of Home Agents is empty, the node simply drops the packet. The Home Agent answers using its own address, and includes an "under attack" cookie, in accordance with RFC 4306 [7]. The Mobile Node notes the Home Agent address and resend the IKE_SA_INIT message to the Home Agent, along with the cookie.

The resulting IKE_SA_INIT transaction is the following:

Initiator                             Responder ("best" HA)
--------------------------------------------------------------------------
(IP_I:500 -> ANYCAST:500)            (IP_R:500 -> IP_I:500)
HDR(A,0), SAi1, KEi, Ni  -->         HDR(A,0), N(COOKIE)

(IP_I:500 -> IP_R:500)               (IP_R:500 -> IP_I:500)
HDR(A,0), N(COOKIE), SAi1, KEi, Ni  -->         HDR(A,B), SAr1, KEr, Nr,[CERTREQ]

(IP_I:500 -> IP_R:500)               (IP_I:500 -> IP_R:500)
HDR(A,B), SK {IDi, [CERT,] [CERTREQ,] [IDr,]AUTH, SAi2, TSi, TSr} -->
Note that this procedure requires the implementation of anycast forwarding in such a way that the Home Agent can distinguish between an IKE_SA_INIT forwarded through an anycast address and one sent directly from the Mobile Node. Home Agents SHOULD NOT include an "under attack" cookie unless the IKE_SA_INIT was forwarded through an anycast address or the Home Agent believes that it is, in fact, under attack, in order to maintain conformance with RFC 4306 for other applications.

5.3. Home Address assignment

Home Address assignment is performed during the IKEv2 exchange. The Home Address can be assigned directly by the Home Agent or can be auto-configured by the Mobile Node.

5.3.1. Home Address assignment by the Home Agent

When the Mobile Node runs IKEv2 with its Home Agent, it can request a HoA through the Configuration Payload in the IKE_AUTH exchange by including an INTERNAL_IP6_ADDRESS attribute. When the Home Agent processes the message, it allocates a HoA and sends it a CFG_REPLY message. The Home Agent could consult a DHCP server on the home link for the actual home address allocation. This is explained in detail in [6].

5.3.2. Home Address auto-configuration by the Mobile Node

With the type of assignment described in the previous section, the Home Address cannot be generated based on Cryptographically Generated Addresses (CGAs) [11] or based on the privacy extensions for stateless auto-configuration [12]. However, the Mobile Node might want to have an auto-configured HoA based on these mechanisms. It is worthwhile to mention that the auto-configuration procedure described in this section cannot be used in some possible deployments, since the Home Agents might be provisioned with pools of allowed Home Addresses.

In the simplest case, the Mobile Node is provided with a pre-configured home prefix and home prefix length. In this case the Mobile Node creates a Home Address based on the pre-configured prefix and sends it to the Home Agent including an INTERNAL_IP6_ADDRESS attribute in a Configuration Payload of type CFG_REQUEST. If the Home Address is valid, the Home Agent replies with a CFG_REPLY, including an INTERNAL_IP6_ADDRESS with the same
address. If the Home Address provided by the Mobile Node is not valid, the Home Agent assigns a different Home Address including an INTERNAL_IP6_ADDRESS attribute with a new value. According to [7] the Mobile Node MUST use the address sent by the Home Agent. Later, if the Mobile Node wants to use an auto-configured Home Address (e.g. based on CGA), it can run Mobile Prefix Discovery, obtain a prefix, auto-configure a new Home Address and then perform a new CREATE_CHILD_SA exchange.

If the Mobile Node is not provided with a pre-configured Home Prefix, the Mobile cannot simply propose an auto-configured HoA in the Configuration Payload since the Mobile Node does not know the home prefix before the start of the IKEv2 exchange. The Mobile Node must obtain the home prefix and the home prefix length before it can configure a home address.

One simple solution would be for the Mobile Node to just assume that the prefix length on the home link is 64 bits and extract the home prefix from the Home Agent’s address. The disadvantage with this solution is that the home prefix cannot be anything other than /64. Moreover, this ties the prefix on the home link and the Home Agent’s address, but, in general, a Home Agent with a particular address should be able to serve a number of prefixes on the home link, not just the prefix from which its address is configured.

Another solution would be for the Mobile Node to assume that the prefix length on the home link is 64 bits and send its interface identifier to the Home Agent in the INTERNAL_IP6_ADDRESS attribute within the CFG_REQ payload. Even though this approach does not tie the prefix on the home link and the Home Agent’s address, it still requires that the home prefix length is 64 bits.

For this reason the Mobile Node needs to obtain the home link prefixes through the IKEv2 exchange. In the Configuration Payload during the IKE_AUTH exchange, the Mobile Node includes the MIP6_HOME_PREFIX attribute in the CFG_REQUEST message. The Home Agent, when it processes this message, should include in the CFG_REPLY payload prefix information for one prefix on the home link. This prefix information includes the prefix length (see section 8.2). The Mobile Node auto-configures a Home Address from the prefix returned in the CFG_REPLY message and runs a CREATE_CHILD_SA exchange to create security associations for the new Home Address.

As mentioned before in this document, there are deployments where auto-configuration of the Home Address cannot be used. In this case, when the Home Agent receives a CFG_REQUEST including a MIP6_HOME_PREFIX attribute, in the subsequent IKE response it includes a Notify Payload type "USE_ASSIGNED_HoA" and the related Home Address in a INTERNAL_IP6_ADDRESS attribute. If the Mobile
Node gets a "USE_ASSIGNED_HoA" Notify Payload in response to the Configuration Payload containing the MIP6_HOME_PREFIX attribute, it looks for an INTERNAL_IP6_ADDRESS attribute and MUST use the address contained in it in the subsequent CREATE_CHILD_SA exchange.

When the Home Agent receives a Binding Update for the Mobile Node, it performs proxy DAD for the auto-configured Home Address. If DAD fails, the Home Agent rejects the Binding Update. If the Mobile Node receives a Binding Acknowledgement with status 134 (DAD failed), it MUST stop using the current Home Address, configure a new HoA, and then run IKEv2 CREATE_CHILD_SA exchange to create security associations based on the new HoA. The Mobile Node does not need to run IKE_INIT and IKE_AUTH exchanges again. Once the necessary security associations are created, the Mobile Node sends a Binding Update for the new Home Address.

It is worth noting that with this mechanism, the prefix information carried in MIP6_HOME_PREFIX attribute includes only one prefix and does not carry all the information that is typically present when received through a IPv6 router advertisement. Mobile Prefix Discovery, specified in RFC 3775 [2], is the mechanism through which the Mobile Node can get all prefixes on the home link and all related information. That means that MIP6_HOME_PREFIX attribute is only used for Home Address auto-configuration and does not replace the usage of Mobile Prefix Discovery for the purposes detailed in RFC 3775.

5.4. Authorization and Authentication with MSA

In a scenario where the Home Agent is discovered dynamically by the Mobile Node, it is very likely that the Home Agent is not able to verify by its own the credentials provided by the Mobile Node during the IKEv2 exchange. Moreover, the mobility service needs to be explicitly authorized based on the user’s profile. As an example, the Home Agent might not be aware of whether the mobility service can be granted at a particular time of the day or when the credit of the Mobile Node is going to expire.

Due to all these reasons, the Home Agent may need to contact the MSA in order to authenticate the Mobile Node and authorize mobility service. This can be accomplished based on a Public Key Infrastructure if certificates are used and a PKI is deployed by the MSP and MSA. On the other hand, if the Mobile Node is provided with other types of credentials, the AAA infrastructure must be used.
The definition of this backend communication is out of the scope of this document. In [14] a list of goals for such a communication is provided.
6. Home Address registration in the DNS

In order that the Mobile Node is reachable through its dynamically assigned Home Address, the DNS needs to be updated with the new Home Address. Since applications make use of DNS lookups on FQDN to find a node, the DNS update is essential for providing IP reachability to the Mobile Node, which is the main purpose of the Mobile IPv6 protocol. The need for DNS updating is not discussed in RFC 3775 since it assumes that the Mobile Node is provisioned with a static Home Address. However, when a dynamic Home Address is assigned to the Mobile Node, any existing DNS entry becomes invalid and the Mobile Node becomes unreachable unless a DNS update is performed.

Since the DNS update must be performed securely in order to prevent attacks or modifications from malicious nodes, the node performing this update must share a security association with the DNS server. Having all possible Mobile Nodes sharing a security association with the DNS servers of the MSP might be cumbersome from an administrative perspective. Moreover, even if a Mobile Node has a security association with a DNS server of its MSP, an address authorization issue comes into the picture. A detailed analysis of possible threats against DNS update is provided in section 9.5.

Therefore, due to security and administrative reasons, it is RECOMMENDED that the Home Agent perform DNS entry updates for the Mobile Node. For this purpose the Mobile Node MAY include a new mobility option in the Binding Update, the DNS Update option, with the flag R not set in the option. This option is defined in section 8 and includes the FQDN that needs to be updated. After receiving the Binding Update, the Home Agent MUST update the DNS entry with the identifier provided by the Mobile Node and the Home Address included in the Home Address Option. The procedure for sending a dynamic DNS update message is specified in [16]. The dynamic DNS update SHOULD be performed in a secure way; for this reason, the usage of TKEY and TSEC or DNSSEC is recommended (see section 9.5. for details). As soon as the Home Agent has updated the DNS, it MUST send a Binding Acknowledgement message to the Mobile Node including the DNS Update mobility option with the correct value in the Status field (see section 8.1).

This procedure can be performed directly by the Home Agent if the Home Agent has a security association with the domain specified in the Mobile Node’s FQDN.

On the other hand, if the Mobile Node wants to be reachable through a FQDN that belongs to the MSA, the Home Agent and the DNS server that must be updated belong to different administrative domains. In this case the Home Agent may not share a security association with the DNS server and the DNS entry update can be
performed by the AAA server of the MSA. In order to accomplish this, the Home Agent sends to the AAA server the FQDN-HoA pair through the AAA protocol. This message is proxied by the AAA infrastructure of the MSP and is received by the AAA server of the MSA. The AAA server of the MSA perform the DNS update based on [16]. Notice that, even in this case, the Home Agent is always required to perform a DNS update for the reverse entry, since this is always performed in the DNS server of the MSP. The detailed description of the communication between Home Agent and AAA is out of the scope of this document. More details are provided in [14].

A mechanism to remove stale DNS entries is needed. A DNS entry becomes stale when the related Home Address is no longer used by the Mobile Node. To remove a DNS entry, the Mobile Node includes in the Binding Update the DNS Update mobility option, with the flag R set in the option. After receiving the Binding Update, the Home Agent MUST remove the DNS entry identified by the FQDN provided by the Mobile Node and the Home Address included in the Home Address Option. The procedure for sending a dynamic DNS update message is specified in [16]. As mentioned above, the dynamic DNS update SHOULD be performed in a secure way; for this reason, the usage of TKEY and TSEC or DNSSEC is recommended (see section 9.5. for details).

If there is no explicit de-registration BU from the Mobile Node, then the HA MAY use the binding cache entry expiration as a trigger to remove the DNS entry.
7. Summary of Bootstrapping Protocol Flow

The message flow of the whole bootstrapping procedure when the dynamic DNS update is performed by the Home Agent is depicted in Figure 4.

```
+----+                  +----+              +-----+
| MN |                  | HA |              | DNS |
+----+                  +----+              +-----+
IKEv2 exchange
(HoA configuration)
<======================>
BU (DNS update option)
---------------------->
DNS update
<--------------------->
BA (DNS update option)
<---------------------->
```

Figure 4 - Dynamic DNS update by the HA

Figure 5 shows the message flow of the whole bootstrapping procedure when the dynamic DNS update is performed by the AAA server of the MSA.
Notice that, even in this last case, the Home Agent is always required to perform a DNS update for the reverse entry, since this is always performed in the DNS server of the MSP. This is not depicted in Figure 5.
8. Option and Attribute Format

8.1. DNS Update mobility option

0                   1                   2                   3
0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
|  Option Type  | Option Length |
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
|   Status      |R|  Reserved   |     MN identity (FQDN) ...
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+

o Option Type - DNS-UPDATE-TYPE to be defined by IANA

o Option Length - 8 bit unsigned integer indicating the length of the option excluding the type and length fields

o Status - 8 bit unsigned integer indicating the result of the dynamic DNS update procedure. This field MUST be set to 0 and ignored by the receiver when the DNS Update mobility option is included in a Binding Update message. When the DNS Update mobility option is included in the Binding Acknowledgement message, values of the Status field less than 128 indicate that the dynamic DNS update was performed successfully by the Home Agent. Values greater than or equal to 128 indicate that the dynamic DNS update was not completed by the HA. The following Status values are currently defined:

0 DNS update performed
128 Reason unspecified
129 Administratively prohibited
130 DNS Update Failed

o R flag - if set the Mobile Node is requesting the HA to remove the DNS entry identified by the FQDN specified in this option and the HoA of the Mobile Node. If not set, the Mobile Node is requesting the HA to create or update a DNS entry with its HoA and the FQDN specified in the option.

o Reserved - these bits are reserved for future purposes and MUST be set to 0.

o MN identity - the identity of the Mobile Node to be used by the Home Agent to send a Dynamic DNS update. It is a variable length field.
8.2. MIP6_HOME_PREFIX attribute

The MIP6_HOME_PREFIX attribute is included in the IKEv2 CFG_REQUEST by the Mobile Node to ask the Home Agent for the home prefix and is included in the CFG_REPLY by the Home Agent to provide the Mobile Node with home prefix and home prefix length. The format of this attribute is equal to the format of the Configuration Attributes defined in [7] and is depicted below.

```
+---------------+---------------+---------------+
| R | Attribute Type |
+---------------+---------------+---------------+
| Length        | Prefix Length |
+---------------+---------------+---------------+
| home prefix   |
+---------------+---------------+---------------+
| Prefix Lifetime |
+---------------+---------------+---------------+
```

- **Reserved (1 bit)** - This bit MUST be set to zero and MUST be ignored on receipt.
- **Attribute Type (15 bits)** - A unique identifier for the MIP6_HOME_PREFIX attribute. To be assigned by IANA.
- **Length (2 octets)** - Length in octets of Value field (home prefix and Prefix Length). This is multi-valued and can be 0 or 17.
- **Prefix Length (2 octets)** - The length in bits of the home prefix specified in the field Home Prefix.
- **Home Prefix (16 octets)** - The prefix of the home link through which the Mobile Node must auto-configure its Home Address.
- **Prefix Lifetime (4 octets)** - The lifetime of the Home Prefix.

When the MIP6_HOME_PREFIX attribute is included by the Mobile Node in the CFG_REQUEST payload, the value of the Length field is 0. On the other hand, when the MIP6_HOME_PREFIX attribute is included in the CFG_REPLY payload by the Home Agent, the value of the Length field is 17 and the attribute contains also the Home Prefix and the Prefix Length fields.
9. Security Considerations

9.1. HA Address Discovery

Use of DNS for address discovery carries certain security risks. DNS transactions in the Internet are typically done without any authentication of the DNS server by the client or of the client by the server. There are two risks involved:

1) A legitimate client obtains a bogus Home Agent address from a bogus DNS server. This is sometimes called a "pharming" attack,

2) An attacking client obtains a legitimate Home Agent address from a legitimate server.

The risk in Case 1 is mitigated because the Mobile Node is required to conduct an IKE transaction with the Home Agent prior to performing a Binding Update to establish Mobile IPv6 service. According to the IKEv2 specification [7], the responder must present the initiator with a valid certificate containing the responder’s public key, and the responder to initiator IKE_AUTH message must be protected with an authenticator calculated using the public key in the certificate. Thus, an attacker would have to set up both a bogus DNS server and a bogus Home Agent, and provision the Home Agent with a certificate that a victim Mobile Node could verify. If the Mobile Node can detect that the certificate is not trustworthy, the attack will be foiled when the Mobile Node attempts to set up the IKE SA.

The risk in Case 2 is limited for a single Mobile Node to Home Agent transaction if the attacker does not possess proper credentials to authenticate with the Home Agent. The IKE SA establishment will fail when the attacking Mobile Node attempts to authenticate itself with the Home Agent. Regardless of whether the Home Agent utilizes EAP or host-side certificates to authenticate the Mobile Node, the authentication will fail unless the Mobile Node has valid credentials.

Another risk exists in Case 2 because the attacker may be attempting to propagate a DoS attack on the Home Agent. In that case, the attacker obtains the Home Agent address from the DNS, then propagates the address to a network of attacking hosts that bombard the Home Agent with traffic. This attack is not unique to the bootstrapping solution, however, it is actually a risk that any Mobile IPv6 Home Agent installation faces. In fact, the risk is faced by any service in the Internet that distributes a unicast globally routable address to clients. Since Mobile IPv6 requires that the Mobile Node communicate through a globally routable unicast address of a Home Agent, it is possible that the Home Agent address could be propagated to an attacker by various means (theft of the Mobile Node, malware installed on the Mobile Node).
evil intent of the Mobile Node owner him/herself, etc.) even if
the home address is manually configured on the Mobile Node.
Consequently, every Mobile IPv6 Home Agent installation will
likely be required to mount anti-DoS measures. Such measures
include overprovisioning of links to and from Home Agents and of
Home Agent processing capacity, vigilant monitoring of traffic on
the Home Agent networks to detect when traffic volume increases
abnormally indicating a possible DoS attack, and hot spares that
can quickly be switched on in the event an attack is mounted on an
operating collection of Home Agents. DoS attacks of moderate
intensity should be foiled during the IKEv2 transaction. IKEv2
implementations are expected to generate their cookies without any
saved state, and to time out cookie generation parameters
frequency, with the timeout value increasing if a DoS attack is
suspected. This should prevent state depletion attacks, and should
assure continued service to legitimate clients until the practical
limits on the network bandwith and processing capacity of the Home
Agent network are reached.

Explicit security measures between the DNS server and host, such
DNSSEC [18] or TSIG/TKEY [19] [20] can mitigate the risk of 1) and
2), but these security measures are not widely deployed on end
nodes. These security measures are not sufficient to protect the
Home Agent address against DoS attack, however, because a node
having a legitimate security association with the DNS server could
nevertheless intentionally or inadvertently cause the Home Agent
address to become the target of DoS.

Finally notice that assignment of an home agent from the serving
network access provider’s (local home agent) or a home agent from
a nearby network (nearby home agent) may set up the potential to
compromise a mobile node’s location privacy. However, since a
standardized mechanism of assigning local or nearby home agents is
out of scope for this document, it is not possible to present
detailed security considerations. Please see other drafts that
contain detailed mechanisms for localized home agent assignment,
such as [17], for information on the location privacy properties
of particular home agent assignment mechanisms.

Security considerations for discovering HA using DHCP are covered
in draft-jang-dhc-haopt-01 [15].

9.2. Home Address Assignment through IKEv2

Mobile IPv6 bootstrapping assigns the home address through the
IKEv2 transaction. The Mobile Node can either choose to request an
address, similar to DHCP, or the Mobile Node can request a prefix
on the home link then auto-configure an address.

authorization of a home address received during a Binding Update.
The Home Agent MUST set up authorization by linking the home address to the identity of the IPsec SAs used to authenticate the Binding Update message. The linking MUST be done either during the IKE_AUTH phase or CREATE_CHILD_SA phase when the IPsec SAs are constructed.

If the address is auto-configured, RFC 3775 requires the Home Agent to proxy-defend the address on the home link after the Mobile Node performs the initial Binding Update. Since it is not currently possible to securely proxy CGAs using SEND, attacks on address resolution for Neighbor Discovery listed in RFC 3756 are possible on dynamically assigned home addresses that are proxied by the Home Agent.

9.3. SA Establishment Using EAP Through IKEv2

Security considerations for authentication of the IKE transaction using EAP are covered in draft-ietf-mip6-ikev2-ipsec [6].

9.4. Back End Security Between the HA and AAA Server

Some deployments of Mobile IPv6 bootstrapping may use an AAA server to handle authorization for mobility service. This process has its own security requirements, but the back end protocol for Home Agent to AAA server interface is not covered in this draft. Please see draft-ietf-mip6-aaa-ha-goals [14] for a discussion of this interface.

9.5. Dynamic DNS Update

Mobile IPv6 bootstrapping recommends the Home Agent to update the Mobile Node’s FQDN with a dynamically assigned home address rather than have the Mobile Node itself do it (see Section 6 above). This choice was motivated by a concern for preventing redirection-based flooding attacks (see draft-ietf-mip6-ro-sec [21] for more information about redirection-based flooding attacks and the role preventing them played in the design of Mobile IPv6 route optimization security). Exactly as for route optimization, it is possible for a node that is the legitimate owner of a DNS FQDN - in the sense that it has a security association with the DNS server allowing it to perform dynamic DNS update of its FQDN - to bind its FQDN to the address of a victim, then redirect large volumes of traffic at the victim. The attack may be propagated without the owner’s knowledge, for example, if the node is compromised by malware, or it may be intentional if the node itself is the attacker.

While it is possible to prevent redirection attacks through ingress filtering on access routers, ISPs have little or no incentive to deploy ingress filtering. In some cases, if an attack could result in substantial financial gain, it is even possible
that a corrupt ISP may have an incentive not to deploy ingress filters such as has been the case for spam. Consequently, the security for dynamic Mobile Node FQDN update has been assigned to the Home Agent, where active network administration and vigilant defense measures are more likely to (but are not assured of) mitigating problems, and the owner of the Mobile Node is more likely to detect a problem if it occurs.

If a Home Agent performs dynamic DNS update on behalf of the Mobile Node directly with the DNS server, the Home Agent MUST have a security association of some type with the DNS server. The security association MAY be established either using DNSSEC [18] or TSIG/TKEY [19][20]. A security association is required even if the DNS server is in the same administrative domain as the Home Agent. The security association SHOULD be separate from the security associations used for other purposes, such as AAA.

In the case where the Mobility Service Provider is different from the Mobility Service Authorizer, the network administrators may want to limit the number of cross-administrative domain security associations. If the Mobile Node’s FQDN is in the Mobility Service Authorizer’s domain, since a security association for AAA signaling involved in mobility service authorization is required in any case, the Home Agent can send the Mobile Node’s FQDN to the AAA server under the HA-AAA server security association, and the AAA server can perform the update. In that case, a security association is required between the AAA server and DNS server for the dynamic DNS update. See draft-ietf-mip6-aaa-ha-goals [14] for a deeper discussion of the Home Agent to AAA server interface.

Regardless of whether the AAA server or Home Agent performs DNS update, the authorization of the Mobile Node to update a FQDN MUST be checked prior to the performance of the update. It is an implementation issue as to how authorization is determined. However, in order to allow this authorization step, the Mobile Node MUST use a FQDN as the IDi in IKE_AUTH step of the IKEv2 exchange. The FQDN MUST be the same that will be provided by the Mobile Node in the DNS Update Option. This allows the Home Agent to get authorization information about the Mobile Node’s FQDN via the AAA back end communication performed during IKEv2 exchange. The outcome of this step will give the Home Agent the necessary information to authorize the DNS update request of the Mobile Node. See draft-ietf-mip6-aaa-ha-goals [14] for details about the communication between the AAA server and the Home Agent needed to perform the authorization. Notice that if certificates are used in IKEv2, the authorization information about the FQDN for DNS update MUST be present in the certificate provided by the Mobile Node.
10. IANA Considerations

This document defines a new Mobility Option and a new IKEv2 Configuration Attribute Type.

The following values should be assigned:

- from "Mobility Option" namespace ([2]): DNS-UPDATE-TYPE (section 8.1)
- from "IKEv2 Configuration Payload Attribute Types" namespace ([7]): MIP6_HOME_PREFIX attribute (section 8.2)
- from "IKEv2 Notify Payload Error Types" namespace ([7]): USE_ASSIGNED_HoA error type (section 5.3.2)
11. Contributors

This contribution is a joint effort of the bootstrapping solution design team of the MIP6 WG. The contributors include Basavaraj Patil, Alpesh Patel, Jari Arkko, James Kempf, Yoshihiro Ohba, Gopal Dommety, Alper Yegin, Junghoon Jee, Vijay Devarapalli, Kuntal Chowdury, Julien Bournelle.
