Network Access Control List (ACL) YANG Data Model
draft-ietf-netmod-acl-model-18

Abstract

This document defines a data model for Access Control List (ACL). An ACL is a user-ordered set of rules, used to configure the forwarding behavior in device. Each rule is used to find a match on a packet, and define actions that will be performed on the packet.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at https://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on September 16, 2018.

1. Introduction

Access Control List (ACL) is one of the basic elements used to configure device forwarding behavior. It is used in many networking technologies such as Policy Based Routing, Firewalls etc.

An ACL is an user-ordered set of rules, that is used to filter traffic on a networking device. Each rule is represented by an Access Control Entry (ACE).

Each ACE has a group of match criteria and a group of action criteria.

The match criteria allows for definition of packet headers and metadata, all of which must be true for the match to occur.
o Packet header matches apply to fields visible in the packet such as address or Class of Service (CoS) or port numbers.

o In case a vendor supports it, metadata matches apply to fields associated with the packet but not in the packet header such as input interface or overall packet length

The actions specify what to do with the packet when the matching criteria is met. These actions are any operations that would apply to the packet, such as counting, policing, or simply forwarding. The list of potential actions is unbounded depending on the capabilities of the networking devices.

Access Control List is also widely knowns as ACL (pronounce as [ak-uhl]) or Access List. In this document, Access Control List, ACL and Access List are used interchangeably.

The matching of filters and actions in an ACE/ACL are triggered only after application/attachment of the ACL to an interface, VRF, vty/tty session, QoS policy, routing protocols amongst various other config attachment points. Once attached, it is used for filtering traffic using the match criteria in the ACE’s and taking appropriate action(s) that have been configured against that ACE. In order to apply an ACL to any attachment point other than an interface, vendors would have to augment the ACL YANG model.

Editorial Note (To be removed by RFC Editor)

This draft contains many placeholder values that need to be replaced with finalized values at the time of publication. This note summarizes all of the substitutions that are needed. Please note that no other RFC Editor instructions are specified anywhere else in this document.

Artwork in this document contains shorthand references to drafts in progress. Please apply the following replacements

o "XXXX" --> the assigned RFC value for this draft both in this draft and in the YANG models under the revision statement.

o Revision date in model, in the format 2018-03-15 needs to get updated with the date the draft gets approved. The date also needs to get reflected on the line with <CODE BEGINS>.

o Replace "I-D.ietf-netmod-yang-tree-diagrams" with the assigned RFC number.
1.1. Definitions and Acronyms

ACE: Access Control Entry
ACL: Access Control List
CoS: Class of Service
DSCP: Differentiated Services Code Point
ICMP: Internet Control Message Protocol
IP: Internet Protocol
IPv4: Internet Protocol version 4
IPv6: Internet Protocol version 6
MAC: Media Access Control
TCP: Transmission Control Protocol
UDP: User Datagram Protocol

1.2. Terminology

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [RFC2119] [RFC8174] when, and only when, they appear in all capitals, as shown here.

1.3. Tree Diagram

For a reference to the annotations used in tree diagrams included in this draft, please see YANG Tree Diagrams [I-D.ietf-netmod-yang-tree-diagrams].

2. Problem Statement

This document defines a YANG [RFC7950] data model for the configuration of ACLs. It is very important that model can be used easily by applications/attachments.

ACL implementations in every device may vary greatly in terms of the filter constructs and actions that they support. Therefore this draft proposes a model that can be augmented by standard extensions and vendor proprietary models.
3. Understanding ACL’s Filters and Actions

Although different vendors have different ACL data models, there is a common understanding of what Access Control List (ACL) is. A network system usually has a list of ACLs, and each ACL contains an ordered list of rules, also known as Access Control Entries (ACE). Each ACE has a group of match criteria and a group of action criteria. The match criteria allows for definition of packet headers or metadata, if supported by the vendor. Packet header matching applies to fields visible in the packet such as address or CoS or port numbers. Metadata matching applies to fields associated with the packet, but not in the packet header such as input interface, packet length, or source or destination prefix length. The actions can be any sort of operation from logging to rate limiting or dropping to simply forwarding. Actions on the first matching ACE are applied with no processing of subsequent ACEs.

The model also includes a container to hold overall operational state for each ACL and operational state for each ACE. One ACL can be applied to multiple targets within the device, such as interface of a networking device, applications or features running in the device, etc. When applied to interfaces of a networked device, distinct ACLs are defined for the ingress (input) or egress (output) interface.

This draft tries to address the commonalities between all vendors and create a common model, which can be augmented with proprietary models. The base model is simple in design, and we hope to achieve enough flexibility for each vendor to extend the base model.

The use of feature statements in the model allows vendors to advertise match rules they are capable and willing to support. There are two sets of feature statements a device needs to advertise. The first set of feature statements specify the capability of the device. These include features such as "Device can support ethernet headers" or "Device can support of IPv4 headers". The second set of feature statements specify the combinations of headers the device is willing to support. These include features such as "Plain IPv6 ACL supported" or "Ethernet, IPv4 and IPv6 ACL combinations supported".

3.1. ACL Modules

There are two YANG modules in the model. The first module, "ietf-access-control-list", defines generic ACL aspects which are common to all ACLs regardless of their type or vendor. In effect, the module can be viewed as providing a generic ACL "superclass". It imports the second module, "ietf-packet-fields". The match container in "ietf-access-control-list" uses groupings in "ietf-packet-fields" to specify match fields such as port numbers or protocol. The
combination of 'if-feature' checks and 'must' statements allow for
the selection of relevant match fields that a user can define rules
for.

If there is a need to define a new "matches" choice, such as IPFIX
[RFC7011], the container "matches" can be augmented.

4. ACL YANG Models

4.1. IETF Access Control List module

"ietf-access-control-list" module defines the "acls" container that has a list of "acl". Each "acl" has information identifying the access list by a name ("name") and a list ("aces") of rules associated with the "name". Each of the entries in the list ("aces"), indexed by the string "name", has containers defining "matches" and "actions".

The model defines several ACL types and actions in the form of identities and features. Features are used by implementors to select the ACL types the system can support and identities are used to validate the types that have been selected. These types are implicitly inherited by the "ace", thus safeguarding against misconfiguration of "ace" types in an "acl".

The "matches" define criteria used to identify patterns in "ietf-packet-fields". The choice statements within the match container allow for selection of one header within each of "12", "13", or "14" headers. The "actions" define behavior to undertake once a "match" has been identified. In addition to permit and deny for actions, a logging option allows for a match to be logged that can later be used
to determine which rule was matched upon. The model also defines the ability for ACLs to be attached to a particular interface.

Statistics in the ACL can be collected for an "ace" or for an "interface". The feature statements defined for statistics can be used to determine whether statistics are being collected per "ace", or per "interface".

This module imports definitions from Common YANG Data Types [RFC6991], and A YANG Data Model for Interface Management [I-D.ietf-netmod-rfc7223bis].

4.2. IETF Packet Fields module

The packet fields module defines the necessary groups for matching on fields in the packet including ethernet, ipv4, ipv6, and transport layer fields. The "type" node determines which of these fields get included for any given ACL with the exception of TCP, UDP and ICMP header fields. Those fields can be used in conjunction with any of the above layer 2 or layer 3 fields.

Since the number of match criteria is very large, the base draft does not include these directly but references them by 'uses' statement to keep the base module simple. In case more match conditions are needed, those can be added by augmenting choices within container "matches" in ietf-access-control-list.yang model.

This module imports definitions from Common YANG Data Types [RFC6991] and references IP [RFC0791], ICMP [RFC0792], Definition of the Differentiated Services Field in the IPv4 and IPv6 Headers [RFC2474], The Addition of Explicit Congestion Notification (ECN) to IP [RFC3168], IPv6 Scoped Address Architecture [RFC4007], IPv6 Addressing Architecture [RFC4291], A Recommendation for IPv6 Address Text Representation [RFC5952], IPv6 [RFC8200].

  "A field that specifies the length in bytes of the UDP header and UDP data. The minimum length is 8 bytes because that is the length of the header. The field size sets a theoretical limit of 65,535 bytes (8 byte header + 65,527 bytes of data) for a UDP datagram. However the actual limit for the data length, which is imposed by the underlying IPv4 protocol, is 65,507 bytes (65,535 minus 8 byte UDP header minus 20 byte IP header).

In IPv6 jumbograms it is possible to have UDP packets of size greater than 65,535 bytes. RFC 2675 specifies that the length field is set to zero if the length of the UDP header plus UDP data is greater than 65,535.";
}
4.3. An ACL Example

Requirement: Deny tcp traffic from 192.0.2.0/24, destined to 198.51.100.0/24.

Here is the acl configuration xml for this Access Control List:
The acl and aces can be described in CLI as the following:

```
acl ipv4 sample-ipv4-acl
deny tcp 192.0.2.0/24 198.51.100.0/24
```

### 4.4. Port Range Usage and Other Examples

When a lower-port and an upper-port are both present, it represents a range between lower-port and upper-port with both the lower-port and upper-port included. When only a port is present, it represents a port, with the operator specifying the range.

The following XML example represents a configuration where traffic to source ports 16384, 16385, 16386, and 16387 is dropped.
The following XML example represents a configuration where all ping echo requests are dropped.
The following XML example represents a configuration of a single port, port 21 that accepts traffic.
The following XML example represents a configuration specifying all ports that are not equal to 21, that will drop packets destined for those ports.
5. Security Considerations

The YANG module specified in this document defines a schema for data that is designed to be accessed via network management protocol such as NETCONF [RFC6241] or RESTCONF [RFC8040]. The lowest NETCONF layer is the secure transport layer and the mandatory-to-implement secure transport is SSH [RFC6242]. The lowest RESTCONF layer is HTTPS, and the mandatory-to-implement secure transport is TLS [RFC5246].

The NETCONF Access Control Model (NACM [RFC6536]) provides the means to restrict access for particular NETCONF users to a pre-configured subset of all available NETCONF protocol operations and content.

There are a number of data nodes defined in the YANG module which are writable/creatable/deletable (i.e., config true, which is the default). These data nodes may be considered sensitive or vulnerable in some network environments. Write operations (e.g., <edit-config>)}
to these data nodes without proper protection can have a negative effect on network operations.

These are the subtrees and data nodes and their sensitivity/vulnerability:

/acls/acl/aces: This list specifies all the configured access control entries on the device. Unauthorized write access to this list can allow intruders to access and control the system. Unauthorized read access to this list can allow intruders to spoof packets with authorized addresses thereby compromising the system.

6. IANA Considerations

This document registers three URIs and three YANG modules.

6.1. URI Registration

This document registers three URIs in the IETF XML registry [RFC3688]. Following the format in RFC 3688, the following registration is requested to be made:

URI: urn:ietf:params:xml:ns:yang:ietf-access-control-list

Registrant Contact: The IESG.

XML: N/A, the requested URI is an XML namespace.

6.2. YANG Module Name Registration

This document registers three YANG module in the YANG Module Names registry YANG [RFC6020].
7. Acknowledgements

Alex Clemm, Andy Bierman and Lisa Huang started it by sketching out an initial IETF draft in several past IETF meetings. That draft included an ACL YANG model structure and a rich set of match filters, and acknowledged contributions by Louis Fourie, Dana Blair, Tula Kraiser, Patrick Gili, George Serpa, Martin Bjorklund, Kent Watsen, and Phil Shafer. Many people have reviewed the various earlier drafts that made the draft went into IETF charter.

Dean Bogdanovic, Kiran Agrahara Sreenivasa, Lisa Huang, and Dana Blair each evaluated the YANG model in previous drafts separately, and then worked together to created a ACL draft that was supported by different vendors. That draft removed vendor specific features, and gave examples to allow vendors to extend in their own proprietary ACL. The earlier draft was superseded with this updated draft and received more participation from many vendors.

Authors would like to thank Jason Sterne, Lada Lhotka, Juergen Schoenwalder, David Bannister, Jeff Haas, Kristian Larsson and Einar Nilsen-Nygaard for their review of and suggestions to the draft.

Appendix A. Extending ACL model examples

A.1. A company proprietary module example

Module "example-newco-acl" is an example of company proprietary model that augments "ietf-acl" module. It shows how to use 'augment' with an XPath expression to add additional match criteria, action criteria, and default actions when no ACE matches are found. All these are company proprietary extensions or system feature extensions. "example-newco-acl" is just an example and it is expected that vendors will create their own proprietary models.

[module example-newco-acl {
    yang-version 1.1;
    namespace "http://example.com/ns/example-newco-acl";
    prefix example-newco-acl;
    import ietf-access-control-list {
        prefix "acl";
    }
    organization "Newco model group.";
    contact "abc@newco.com";
    description "This YANG module augments IETF ACL Yang.";
    revision 2018-03-15 {
        description "Creating NewCo proprietary extensions to ietf-acl model";
        reference "RFC XXXX: Network Access Control List (ACL)
        YANG Data Model";
    }
}]

[NOTE: '
' line wrapping for formatting only]
augment "/acl:acls/acl:acl/" +
    "acl:aces/acl:ace/" +
    "acl:matches" {
    description "Newco proprietary simple filter matches";
    choice protocol-payload-choice {
      description "Newco proprietary payload match condition";
      list protocol-payload {
        key value-keyword;
        ordered-by user;
        description "Match protocol payload";
        uses match-simple-payload-protocol-value;
      }
    }
}

choice metadata {
    description "Newco proprietary interface match condition";
    leaf packet-length {
      type uint16;
      description "Match on packet length";
    }
}

augment "/acl:acls/acl:acl/" +
    "acl:aces/acl:ace/" +
    "acl:actions" {
    description "Newco proprietary simple filter actions";
    choice action {
      description "";
      case count {
        description "Count the packet in the named counter";
        leaf count {
          type uint32;
          description "Count";
        }
      }
      case policer {
        description "Name of policer to use to rate-limit traffic";
        leaf policer {
          type string;
          description "Name of the policer";
        }
      }
      case hierarchical-policer {
        leaf hierarchitacl-policer {
          type string;
          description "Name of the hierarchical policer.";
        }
      }
    }
}
The following figure is the tree diagram of example-newco-acl. In this example, /ietf-acl:acls/ietf-acl:acl/ietf-acl:aces/ietf-acl:ace/ietf-acl:matches are augmented with two new choices, protocol-
payload-choice and metadata. The protocol-payload-choice uses a grouping with an enumeration of all supported protocol values. Metadata matches apply to fields associated with the packet but not in the packet header such as overall packet length. In another example, /ietf-acl:acls/ietf-acl:acl/ietf-acl:aces/ietf-acl:ace/ietf-acl:actions are augmented with a new choice of actions.

  augment /acl:acls/acl:acl/acl:aces/acl:ace/acl:actions:
    +--rw default-action?   identityref

A.2. Linux nftables

As Linux platform is becoming more popular as networking platform, the Linux data model is changing. Previously ACLs in Linux were highly protocol specific and different utilities were used (iptables, ip6tables, arptables, ebtables), so each one had separate data model. Recently, this has changed and a single utility, nftables, has been developed. With a single application, it has a single data model for firewall filters and it follows very similarly to the ietf-access-control list module proposed in this draft. The nftables support input and output ACEs and each ACE can be defined with match and action.

The example in Section 4.3 can be configured using nftable tool as below.
nft add table ip filter
nft add chain filter input
nft add rule ip filter input ip protocol tcp ip saddr \n192.0.2.1/24 drop

The configuration entries added in nftable would be.

table ip filter {
  chain input {
    ip protocol tcp ip saddr 192.0.2.1/24 drop
  }
}

We can see that there are many similarities between Linux nftables and IETF ACL YANG data models and its extension models. It should be fairly easy to do translation between ACL YANG model described in this draft and Linux nftables.

A.3. Ethertypes

The ACL module is dependent on the definition of ethertypes. IEEE owns the allocation of those ethertypes. This model is being included here to enable definition of those types till such time that IEEE takes up the task of publication of the model that defines those ethertypes. At that time, this model can be deprecated.

<CODE BEGINS> file "ietf-ethertypes@2018-03-15.yang"

module ietf-ethertypes {
  namespace "urn:ietf:params:xml:ns:yang:ietf-ethertypes";
  prefix ethertypes;

  organization
    "IETF NETMOD (NETCONF Data Modeling Language)";

  contact
    "WG Web:  <http://tools.ietf.org/wg/netmod/>
           WG List:  <mailto:netmod@ietf.org>
    "Editor:  Mahesh Jethanandani
              <mjethanandani@gmail.com>"

  description
    "This module contains the common definitions for the
     Ethertype used by different modules. It is a
     placeholder module, till such time that IEEE
     starts a project to define these Ethertypes"
and publishes a standard.

At that time this module can be deprecated.
