Abstract

This document defines two strategies for handling long lines in width-bounded text content. One strategy is based on the historical use of a single backslash (\) character to indicate where line-folding has occurred, with the continuation occurring with the first non-space (\ ') character on the next line. The second strategy extends the first strategy by adding a second backslash character to identify where the continuation begins and is thereby able to handle cases not supported by the first strategy. Both strategies use a self-describing header enabling automated reconstitution of the original content.

Editorial Note (To be removed by RFC Editor)

Please be aware that this document uses throughout the five-character text sequence located between the following two double-quotes: "(\ "). It has been observed that some renderings of this text sequence produces a natural line break at the space character in the middle, thus causing "(" to appear at the end of the first line and ")" to appear at the beginning of the next line. Such a line-break is confusing and should not occur in the RFC output formats.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at https://datatracker.ietf.org/drafts/current/.
Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on May 6, 2020.

1. Introduction

[RFC7994] sets out the requirements for plain-text RFCs and states that each line of an RFC (and hence of an Internet-Draft) must be limited to 72 characters followed by the character sequence that denotes an end-of-line (EOL).

Internet-Drafts and RFCs often include example text or code fragments. Many times the example text or code exceeds the 72 character line-length limit. The 'xml2rfc' [xml2rfc] utility, at the time of this document’s publication, does not attempt to wrap the content of such inclusions, simply issuing a warning whenever lines exceed 69 characters. Historically, there has been no RFC-Editor-recommended convention in place for how to handle long lines in such inclusions, other than advising authors to clearly indicate what manipulation has occurred.

This document defines two strategies for handling long lines in width-bounded text content. One strategy is based on the historical use of a single backslash (‘\’) character to indicate where line-folding has occurred, with the continuation occurring with the first non-space (‘ ’) character on the next line. The second strategy extends the first strategy by adding a second backslash character to identify where the continuation begins and is thereby able to handle
cases not supported by the first strategy. Both strategies use a self-describing header enabling automated reconstitution of the original content.

The strategies defined in this document work on any text content, but are primarily intended for a structured sequence of lines, such as would be referenced by the <sourcecode> element defined in Section 2.48 of [RFC7991], rather than for two-dimensional imagery, such as would be referenced by the <artwork> element defined in Section 2.5 of [RFC7991].

Note that text files are represented as lines having their first character in column 1, and a line length of N where the last character is in the Nth column and is immediately followed by an end of line character sequence.

2. Applicability Statement

The formats and algorithms defined in this document may be used in any context, whether for IETF documents or in other situations where structured folding is desired.

Within the IETF, this work primarily targets the xml2rfc v3 <sourcecode> element (Section 2.48 of [RFC7991]) and the xml2rfc v2 <artwork> element (Section 2.5 of [RFC7749]) that, for lack of a better option, is currently used for both source code and artwork. This work may also be used for the xml2rfc v3 <artwork> element (Section 2.5 of [RFC7991]) but, as described in Section 5.1, it is generally not recommended.

3. Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [RFC2119] [RFC8174] when, and only when, they appear in all capitals, as shown here.

4. Goals

4.1. Automated Folding of Long Lines in Text Content

Automated folding of long lines is needed in order to support drafts that are dynamically compiled to include content with potentially unconstrained line lengths. For instance, the build process may wish to include content from other local files or dynamically generated by some external process. Both of these cases are discussed next.
Many drafts need to include the content from local files (e.g., XML, JSON, ABNF, ASN.1). Prior to including a file’s content, the build process SHOULD first validate these source files using format-specific validators. In order for such tooling to be able to process the files, the files must be in their original/natural state, which may entail them having some long lines. Thus, these source files need to be folded before inclusion into the XML document, in order to satisfy ‘xml2rfc’ line length limits.

Similarly, drafts sometimes contain dynamically generated output, typically from an external process operating on the same source files discussed in the previous paragraph. For instance, such processes may translate the input format to another format or render a report over or a view of the input file. In some cases, the dynamically generated output may contain lines exceeding the ‘xml2rfc’ line length limits.

In both cases, folding is required and SHOULD be automated to reduce effort and errors resulting from manual processing.

### 4.2. Automated Reconstitution of the Original Text Content

Automated reconstitution of the exact original text content is needed to support validation of text-based content extracted from documents.

For instance, already YANG [RFC7950] modules are extracted from Internet-Drafts and validated as part of the draft-submission process. Additionally, the desire to validate instance examples (i.e., XML/JSON documents) contained within Internet-Drafts has been discussed ([yang-doctors-thread]).

### 5. Limitations

#### 5.1. Not Recommended for Graphical Artwork

While the solution presented in this document works on any kind of text-based content, it is most useful on content that represents source code (XML, JSON, etc.) or, more generally, on content that has not been laid out in two dimensions (e.g., diagrams).

Fundamentally, the issue is whether the text content remains readable once folded. Text content that is unpredictable is especially susceptible to looking bad when folded; falling into this category are most UML diagrams, YANG tree diagrams, and ASCII art in general.

It is NOT RECOMMENDED to use the solution presented in this document on graphical artwork.
5.2. Doesn’t Work as Well as Format-Specific Options

The solution presented in this document works generically for all text-based content, as it only views content as plain text. However, various formats sometimes have built-in mechanisms that are better suited to prevent long lines.

For instance, both the ‘pyang’ [pyang] and ‘yanglint’ [yanglint] utilities have the command line option "--tree-line-length" that can be used to indicate a desired maximum line length for when generating tree diagrams [RFC8340].

In another example, some source formats (e.g., YANG [RFC7950]) allow any quoted string to be broken up into substrings separated by a concatenation character (e.g., ‘+’), any of which can be on a different line.

It is RECOMMENDED that authors do as much as possible within the selected format to avoid long lines.

6. Two Folding Strategies

This document defines two nearly identical strategies for folding text-based content.

The Single Backslash Strategy ('\'): Uses a backslash ('\') character at the end of the line where folding occurs, and assumes that the continuation begins at the first character that is not a space character (' ') on the following line.

The Double Backslash Strategy ('\\'): Uses a backslash ('\') character at the end of the line where folding occurs, and assumes that the continuation begins after a second backslash ('\') character on the following line.

6.1. Comparison

The first strategy produces more readable output, however it is significantly more likely to encounter unfoldable input (e.g., a long line containing only space characters) and, for long lines that can be folded, automation implementations may encounter scenarios that will produce errors without special care.

The second strategy produces less readable output, but is unlikely to encounter unfoldable input, there are no long lines that cannot be folded, and no special care is required for when folding a long line.
6.2. Recommendation

It is RECOMMENDED for implementations to first attempt to fold content using the single backslash strategy and, only in the unlikely event that it cannot fold the input or the folding logic is unable to cope with a contingency occurring on the desired folding column, then fallback to the double backslash strategy.

7. The Single Backslash Strategy (‘\’)

7.1. Folded Structure

Text content that has been folded as specified by this strategy MUST adhere to the following structure.

7.1.1. Header

The header is two lines long.

The first line is the following 46-character string that MAY be surrounded by any number of printable characters. This first line cannot itself be folded.

NOTE: ‘\’ line wrapping per BCP XXX (RFC XXXX)

[Note to RFC Editor: Please replace XXX and XXXX with the numbers assigned to this document and delete this note. Please make this change in multiple places in this document.]

The second line is an empty line, containing only the end-of-line character sequence. This line provides visual separation for readability.

7.1.2. Body

The character encoding is the same as described in Section 2 of [RFC7994], except that, per [RFC7991], tab characters are prohibited.

Lines that have a backslash (‘\’) occurring as the last character in a line are considered "folded".

Exceptionally long lines may be folded multiple times.

7.2. Algorithm

This section describes a process for folding and unfolding long lines when they are encountered in text content.
The steps are complete, but implementations MAY achieve the same result in other ways.

When a larger document contains multiple instances of text content that may need to be folded or unfolded, another process must insert/extract the individual text content instances to/from the larger document prior to utilizing the algorithms described in this section. For example, the `xiax` utility \[xiax\] does this.

### 7.2.1. Folding

Determine the desired maximum line length from input to the line-wrapping process, such as from a command line parameter. If no value is explicitly specified, the value "69" SHOULD be used.

Ensure that the desired maximum line length is not less than the minimum header, which is 46 characters. If the desired maximum line length is less than this minimum, exit (this text-based content cannot be folded).

Scan the text content for horizontal tab characters. If any horizontal tab characters appear, either resolve them to space characters or exit, forcing the input provider to convert them to space characters themselves first.

Scan the text content to ensure at least one line exceeds the desired maximum. If no line exceeds the desired maximum, exit (this text content does not need to be folded).

Scan the text content to ensure no existing lines already end with a backslash (\`) character, as this could lead to an ambiguous result. If such a line is found, and its width is less than the desired maximum, then it SHOULD be flagged for forced folding (folding even though unnecessary). If the folding implementation doesn’t support forced foldings, it MUST exit.

If this text content needs to and can be folded, insert the header described in Section 7.1.1, ensuring that any additional printable characters surrounding the header do not result in a line exceeding the desired maximum.

For each line in the text content, from top-to-bottom, if the line exceeds the desired maximum, or requires a forced folding, then fold the line by:

1. Determine where the fold will occur. This location MUST be before or at the desired maximum column, and MUST NOT be chosen such that the character immediately after the fold is a space (`
2. At the location where the fold is to occur, insert a backslash\n(\'\') character followed by the end of line character sequence.

3. On the following line, insert any number of space (\'\ ')\ncharacters, subject to the resulting line not exceeding the\ndesired maximum.

The result of the previous operation is that the next line starts\nwith an arbitrary number of space (\'\ ') characters, followed by the\ncharacter that was previously occupying the position where the fold\noccurred.

Continue in this manner until reaching the end of the text content.\nNote that this algorithm naturally addresses the case where the\nremainder of a folded line is still longer than the desired maximum,\nand hence needs to be folded again, ad infinitum.

The process described in this section is illustrated by the\"fold_it_1()\" function in Appendix A.

7.2.2. Unfolding

Scan the beginning of the text content for the header described in\nSection 7.1.1. If the header is not present, exit (this text content\ndoes not need to be unfolded).

Remove the 2-line header from the text content.

For each line in the text content, from top-to-bottom, if the line\nhas a backslash (\'\') character immediately followed by the end of\nline character sequence, then the line can be unfolded. Remove the\nbackslash (\'\') character, the end of line character sequence, and\nany leading space (\'\ ') characters, which will bring up the next\nline. Then continue to scan each line in the text content starting\nwith the current line (in case it was multiply folded).

Continue in this manner until reaching the end of the text content.

The process described in this section is illustrated by the\"unfold_it_1()\" function in Appendix A.
8. The Double Backslash Strategy {''\''}

8.1. Folded Structure

Text content that has been folded as specified by this strategy MUST adhere to the following structure.

8.1.1. Header

The header is two lines long.

The first line is the following 47-character string that MAY be surrounded by any number of printable characters. This first line cannot itself be folded.

NOTE: {'\'' line wrapping per BCP XXX (RFC XXXX)

[Note to RFC Editor: Please replace XXX and XXXX with the numbers assigned to this document and delete this note. Please make this change in multiple places in this document.]

The second line is an empty line, containing only the end-of-line character sequence. This line provides visual separation for readability.

8.1.2. Body

The character encoding is the same as described in Section 2 of [RFC7994], except that, per [RFC7991], tab characters are prohibited.

Lines that have a backslash ('\') occurring as the last character in a line immediately followed by the end of line character sequence, when the subsequent line starts with a backslash ('\') as the first non-space (' ') character, are considered "folded".

Exceptionally long lines may be folded multiple times.

8.2. Algorithm

This section describes a process for folding and unfolding long lines when they are encountered in text content.

The steps are complete, but implementations MAY achieve the same result in other ways.

When a larger document contains multiple instances of text content that may need to be folded or unfolded, another process must insert/extract the individual text content instances to/from the larger...
document prior to utilizing the algorithms described in this section. For example, the `xiax` utility [xiax] does this.

8.2.1. Folding

Determine the desired maximum line length from input to the line-wrapping process, such as from a command line parameter. If no value is explicitly specified, the value "69" SHOULD be used.

Ensure that the desired maximum line length is not less than the minimum header, which is 47 characters. If the desired maximum line length is less than this minimum, exit (this text-based content cannot be folded).

Scan the text content for horizontal tab characters. If any horizontal tab characters appear, either resolve them to space characters or exit, forcing the input provider to convert them to space characters themselves first.

Scan the text content to see if any line exceeds the desired maximum. If no line exceeds the desired maximum, exit (this text content does not need to be folded).

Scan the text content to ensure no existing lines already end with a backslash (\') character while the subsequent line starts with a backslash (\') character as the first non-space (') character, as this could lead to an ambiguous result. If such a line is found, and its width is less than the desired maximum, then it SHOULD be flagged for forced folding (folding even though unnecessary). If the folding implementation doesn’t support forced foldings, it MUST exit.

If this text content needs to and can be folded, insert the header described in Section 8.1.1, ensuring that any additional printable characters surrounding the header do not result in a line exceeding the desired maximum.

For each line in the text content, from top-to-bottom, if the line exceeds the desired maximum, or requires a forced folding, then fold the line by:

1. Determine where the fold will occur. This location MUST be before or at the desired maximum column. For forced foldings, the location is between the \'\' and the end of line sequence on the first line.

2. At the location where the fold is to occur, insert a first backslash (\') character followed by the end of line character sequence.
3. On the following line, insert any number of space (' ') characters, subject to the resulting line not exceeding the desired maximum, followed by a second backslash ('\') character.

The result of the previous operation is that the next line starts with an arbitrary number of space (' ') characters, followed by a backslash ('\') character, immediately followed by the character that was previously occupying the position where the fold occurred.

Continue in this manner until reaching the end of the text content. Note that this algorithm naturally addresses the case where the remainder of a folded line is still longer than the desired maximum, and hence needs to be folded again, ad infinitum.

The process described in this section is illustrated by the "fold_it_2()" function in Appendix A.

8.2.2. Unfolding

Scan the beginning of the text content for the header described in Section 8.1.1. If the header is not present, exit (this text content does not need to be unfolded).

Remove the 2-line header from the text content.

For each line in the text content, from top-to-bottom, if the line has a backslash ('\') character immediately followed by the end of line character sequence, and if the next line has a backslash ('\') character as the first non-space (' ') character, then the lines can be unfolded. Remove the first backslash ('\') character, the end of line character sequence, any leading space (' ') characters, and the second backslash ('\') character, which will bring up the next line. Then continue to scan each line in the text content starting with the current line (in case it was multiply folded).

Continue in this manner until reaching the end of the text content.

The process described in this section is illustrated by the "unfold_it_2()" function in Appendix A.

9. Examples

The following self-documenting examples illustrate folded text-based content.

The source text content cannot be presented here, as it would again be folded. Alas, only the results can be provided.
9.1. Example Showing Boundary Conditions

This example illustrates boundary conditions. The input contains seven lines, each line one character longer than the previous line. Numbers for counting purposes. The default desired maximum column value "69" is used.

9.1.1. Using '\'

\9234567890123456789012345678901234567890123456789012345678901234567890
\934567890123456789012345678901234567890123456789012345678901234567890
\01234567890

9.3. Example Showing "Smart" Folding

This example illustrates how readability can be improved via "smart" folding, whereby folding occurs at format-specific locations and format-specific indentations are used.

The text content was manually folded, since the script in the appendix does not implement smart folding.

Note that the headers are surrounded by different printable characters than shown in the script-generated examples.

9.3.1. Using ‘\’
[NOTE: ‘\’ line wrapping per BCP XXX (RFC XXXX)]

```xml
<yang-library
   xmlns="urn:ietf:params:xml:ns:yang:ietf-yang-library"
   <module-set>
     <module>
       <name>ietf-interfaces</name>
       <revision>2018-02-20</revision>
       <namespace>
         urn:ietf:params:xml:ns:yang:ietf-interfaces
       </namespace>
     </module>
     ...<module>
   </module-set>
   ...
</yang-library>
```

Below is the equivalent to the above, but it was folded using the script in the appendix.

========== NOTE: ‘\’ line wrapping per BCP XXX (RFC XXXX) ===========

```xml
<yang-library
   xmlns="urn:ietf:params:xml:ns:yang:ietf-yang-library"
   <module-set>
     <module>
       <name>ietf-interfaces</name>
       <revision>2018-02-20</revision>
       <namespace>
         urn:ietf:params:xml:ns:yang:ietf-interfaces
       </namespace>
     </module>
     ...<module>
   </module-set>
   ...
</yang-library>
```

9.3.2. Using ‘\\’
9.4. Example Showing "Forced" Folding

This example illustrates how invalid sequences in lines that do not have to be folded can be handled via forced folding, whereby the folding occurs even though unnecessary.
The following line exceeds a 68-char max, thus demands folding
123456789012345678901234567890123456789012345678901234567890123456789

This line ends with a backslash \

This line ends with a backslash \
\ This line begins with a backslash

Following is an indented 3x3 block of backslashes:
\ \ \ 
\ \ \ 
\ \ 

The samples below were manually folded, since the script in the appendix does not implement forced folding.

Note that the headers are prefixed by a pound (’#’) character, rather than surrounded by equal (’=’) characters as shown in the script-generated examples.

9.4.1. Using ‘\’

# NOTE: ‘\’ line wrapping per BCP XXX (RFC XXXX)

10. Security Considerations

   This BCP has no Security Considerations.

11. IANA Considerations

   This BCP has no IANA Considerations.

12. References

12.1. Normative References

12.2. Informative References

[xml2rfc] "Xml2rfc generates RFCs and IETF drafts from document source in XML according to the IETF xml2rfc v2 and v3 vocabularies.", <https://pypi.org/project/xml2rfc/>.

Appendix A. Bash Shell Script: rfcfold

This non-normative appendix section includes a Bash [bash] shell script that can both fold and unfold text content using both the single and double backslash strategies described in Section 7 and Section 8 respectively.

This script is intended to be applied to a single text content instance. If it is desired to fold or unfold text content instances within a larger document (e.g., an Internet draft or RFC), then another tool must be used to extract the content from the larger document before utilizing this script.

For readability purposes, this script forces the minimally supported line length to be eight characters longer than the raw header text defined in Section 7.1.1 and Section 8.1.1 so as to ensure that the header can be wrapped by a space (‘ ’) character and three equal (‘=’) characters on each side of the raw header text.

When a TAB character is detected in the input file, this script exits with the error message:

    Error: infile contains a TAB character, which is not allowed.

This script tests for the availability of GNU awk (gawk), in order to test for ASCII-based control characters and non-ASCII characters in the input file (see below). Note that testing revealed flaws in the default version of `awk` on some platforms. As the use of `gawk` is only used to issue warning messages, if `gawk` of not found, this script issues the debug message:

    Debug: no GNU Awk, skipping checks for special characters.

When `gawk` is available (see above) and ASCII-based control characters are detected in the input file, this script issues the warning message:

    Warning: infile contains ASCII control characters (unsupported).

When `gawk` is available (see above) and non-ASCII characters are detected in the input file, this script issues the warning message:

    Warning: infile contains non-ASCII characters (unsupported).

This script does not implement the whitespace-avoidance logic described in Section 7.2.1. In such case, the script will exit with the following message:
Error: infile has a space character occurring on the folding column. This file cannot be folded using the ‘\’ strategy.

While this script can unfold input that contains forced foldings, it is unable to fold files that would require forced foldings. Forced folding is described in Section 7.2.1 and Section 8.2.1. When being asked to fold a file that would require forced folding, the script will instead exit with the following message:

For ‘\’:

Error: infile has a line ending with a ‘\’ character. This file cannot be folded using the ‘\’ strategy without there being false positives produced in the unfolding (i.e., this script does not force-fold such lines, as described in BCP XXX, RFC XXXX).

For ‘\\’:

Error: infile has a line ending with a ‘\’ character followed by a ‘\’ character as the first non-space character on the next line. This script cannot fold this file using ‘\\’ strategy without there being false positives produced in the unfolding (i.e., this script does not force-fold such lines, as described in BCP XXX, RFC XXXX).

Shell-level end-of-line backslash (‘\’) characters have been purposely added to the script so as to ensure that the script is itself not folded in this document, thus simplifying the ability to copy/paste the script for local use. As should be evident by the lack of the mandatory header described in Section 7.1.1, these backslashes do not designate a folded line, such as described in Section 7.

<CODE BEGINS>

#!/bin/bash --posix

# This script may need some adjustments to work on a given system.
# For instance, the utility 'gsed' may need to be installed.
# Also, please be advised that 'bash' (not 'sh') must be used.

Acknowledgements

The authors thank the RFC Editor for confirming that there was previously no set convention, at the time of this document’s publication, for handling long lines in source code inclusions, thus instigating this work.

The authors thank the following folks for their various contributions while producing this document (sorted by first name): Benoit Claise, Gianmarco Bruno, Italo Busi, Joel Jaeggli, Jonathan Hansford, Lou Berger, Martin Bjorklund, and Rob Wilton.
Special acknowledgement to Erik Auerswald for his contributions to the 'rfcfold' script, especially for greatly improving the 'sed' one-liners used therein.
