A YANG Data Model for IP Management
draft-ietf-netmod-ip-cfg-14

Abstract

This document defines a YANG data model for management of IP implementations. The data model includes configuration data and state data.

Status of this Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at http://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on September 29, 2014.

1. Introduction

This document defines a YANG [RFC6020] data model for management of IP implementations.

The data model covers configuration of per-interface IPv4 and IPv6 parameters, and mappings of IP addresses to link-layer addresses. It also provides information about which IP addresses are operationally used, and which link-layer mappings exist. Per-interface parameters are added through augmentation of the interface data model defined in [I-D.ietf-netmod-interfaces-cfg].

1.1. Terminology

The keywords "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14, [RFC2119].

The following terms are defined in [RFC6241] and are not redefined here:

- client
- configuration data
- server
- state data

The following terms are defined in [RFC6020] and are not redefined here:

- augment
- data model
- data node

The terminology for describing YANG data models is found in [RFC6020].

1.2. Tree Diagrams

A simplified graphical representation of the data model is used in this document. The meaning of the symbols in these diagrams is as follows:
o Brackets "[" and "]" enclose list keys.

o Abbreviations before data node names: "rw" means configuration data (read-write) and "ro" state data (read-only).

o Symbols after data node names: "?" means an optional node, "!" means a presence container, and "*" denotes a list and leaf-list.

o Parentheses enclose choice and case nodes, and case nodes are also marked with a colon ":").

o Ellipsis ("...") stands for contents of subtrees that are not shown.
2. IP Data Model

This document defines the YANG module "ietf-ip", which augments the "interface" and "interface-state" lists defined in the "ietf-interfaces" module [I-D.ietf-netmod-interfaces-cfg] with IP specific data nodes, and adds IP specific state data.

The data model has the following structure for IP configuration per interface:

```yang
+--rw if:interfaces
   +--rw if:interface* [name]

   +--rw ipv4!
      |   +--rw enabled?    boolean
      |   +--rw forwarding?  boolean
      |   +--rw mtu?        uint16
      |   +--rw address* [ip]
      |      |   +--rw (subnet)
      |      |      |   +--rw ip:prefix-length? uint8
      |      |      |   +--rw ip:netmask?      yang:dotted-quad
      |      |   +--rw neighbor* [ip]
      |      |      |   +--rw ip:prefix-length       uint8
      |      |      |   +--rw ip:netmask?       yang:dotted-quad
      +--rw ipv6!
      |   +--rw enabled?    boolean
      |   +--rw forwarding?  boolean
      |   +--rw mtu?        uint32
      |   +--rw address* [ip]
      |      |   +--rw ip:prefix-length    uint8
      |      |   +--rw neighbor* [ip]
      |      |      |   +--rw ip:prefix-length     uint8

The data model defines two configuration containers per interface, "ipv4" and "ipv6", representing the IPv4 and IPv6 address families. In each container, there is a leaf "enabled" that controls if the address family is enabled on that interface, and a leaf "forwarding"
that controls if IP packet forwarding for the address family is
enabled on the interface. In each container, there is also a list of
configured addresses, and a list of configured mappings from IP
addresses to link-layer addresses.

The data model has the following structure for IP state per
interface:

```
+--ro if:interfaces-state
   +--ro if:interface* [name]
     ...
     +--ro ipv4!
        +--ro forwarding?   boolean
        +--ro mtu?          uint16
        +--ro address* [ip]
           |  +--ro ip               inet:ipv4-address-no-zone
           |  +--ro (subnet)?
           |     |  +--:(prefix-length)
           |     |     |  +--ro prefix-length?  uint8
           |     |  +--:(netmask)
           |     |     +--ro netmask?         yang:dotted-quad
           |  +--ro origin?          ip-address-origin
        +--ro neighbor* [ip]
           |  +--ro ip                    inet:ipv4-address-no-zone
           |  +--ro link-layer-address?   yang:phys-address
           |  +--ro origin?               neighbor-origin
     +--ro ipv6!
        +--ro forwarding?   boolean
        +--ro mtu?          uint32
        +--ro address* [ip]
           |  +--ro ip               inet:ipv6-address-no-zone
           |  +--ro prefix-length    uint8
           |  +--ro origin?          ip-address-origin
           |  +--ro status?          enumeration
        +--ro neighbor* [ip]
           |  +--ro ip               inet:ipv6-address-no-zone
           |  +--ro link-layer-address?   yang:phys-address
           |  +--ro origin?               neighbor-origin
           |  +--ro is-router?            empty
           |  +--ro state?                enumeration
```

The data model defines two state containers per interface, "ipv4" and
"ipv6", representing the IPv4 and IPv6 address families. In each
container, there is a leaf "forwarding" that indicates if IP packet
forwarding is enabled on that interface. In each container there is
also a list of all addresses in use, and a list of known mappings
from IP addresses to link-layer addresses.
3. Relationship to IP-MIB

If the device implements IP-MIB [RFC4293], each entry in the "ipv4/address" and "ipv6/address" lists is mapped to one ipAddressEntry, where the ipAddressIfIndex refers to the "address" entry's interface.

The IP-MIB defines objects to control IPv6 Router Advertisement. The corresponding YANG data nodes are defined in [I-D.ietf-netmod-routing-cfg].

The entries in "ipv4/neighbor" and "ipv6/neighbor" are mapped to ipNetToPhysicalTable.

The following tables list the YANG data nodes with corresponding objects in the IP-MIB.

<table>
<thead>
<tr>
<th>YANG data node in /if:interfaces/if:interface</th>

5. IANA Considerations

This document registers a URI in the IETF XML registry [RFC3688]. Following the format in RFC 3688, the following registration is requested to be made.

   Registrant Contact: The NETMOD WG of the IETF.

   XML: N/A, the requested URI is an XML namespace.

This document registers a YANG module in the YANG Module Names registry [RFC6020].

   name:       ietf-ip
   prefix:     ip
   reference:  RFC XXXX
6. Security Considerations

The YANG module defined in this memo is designed to be accessed via the NETCONF protocol [RFC6241]. The lowest NETCONF layer is the secure transport layer and the mandatory-to-implement secure transport is SSH [RFC6242]. The NETCONF access control model [RFC6536] provides the means to restrict access for particular NETCONF users to a pre-configured subset of all available NETCONF protocol operations and content.

There are a number of data nodes defined in the YANG module which are writable/creatable/deletable (i.e., config true, which is the default). These data nodes may be considered sensitive or vulnerable in some network environments. Write operations (e.g., edit-config) to these data nodes without proper protection can have a negative effect on network operations. These are the subtrees and data nodes and their sensitivity/vulnerability:

ipv4/enabled and ipv6/enabled: These leaves are used to enable or disable IPv4 and IPv6 on a specific interface. By enabling a protocol on an interface, an attacker might be able to create an unsecured path into a node (or through it if routing is also enabled). By disabling a protocol on an interface, an attacker might be able to force packets to be routed through some other interface or deny access to some or all of the network via that protocol.

ipv4/address and ipv6/address: These lists specify the configured IP addresses on an interface. By modifying this information, an attacker can cause a node to either ignore messages destined to it or accept (at least at the IP layer) messages it would otherwise ignore. The use of filtering or security associations may reduce the potential damage in the latter case.

ipv4/forwarding and ipv6/forwarding: These leaves allow a client to enable or disable the forwarding functions on the entity. By disabling the forwarding functions, an attacker would possibly be able to deny service to users. By enabling the forwarding functions, an attacker could open a conduit into an area. This might result in the area providing transit for packets it shouldn’t or might allow the attacker access to the area bypassing security safeguards.

ipv6/autoconf: The leaves in this branch control the autoconfiguration of IPv6 addresses and in particular whether temporary addresses are used or not. By modifying the corresponding leaves, an attacker might impact the addresses used by a node and thus indirectly the privacy of the users using the
node.

ipv4/mtu and ipv6/mtu: Setting these leaves to very small values can be used to slow down interfaces.
7. Acknowledgments

The author wishes to thank Jeffrey Lange, Ladislav Lhotka, Juergen Schoenwaelder, and Dave Thaler for their helpful comments.
