Generic Protocol Extension for VXLAN
draft-ietf-nvo3-vxlan-gpe-03

Abstract

This draft describes extending Virtual eXtensible Local Area Network (VXLAN), via changes to the VXLAN header, with three new capabilities: support for multi-protocol encapsulation, operations, administration and management (OAM) signaling and explicit versioning.

Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119].

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at http://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on April 28, 2017.

1. Introduction

Virtual eXtensible Local Area Network VXLAN [RFC7348] defines an encapsulation format that encapsulates Ethernet frames in an outer UDP/IP transport. As data centers evolve, the need to carry other protocols encapsulated in an IP packet is required, as well as the need to provide increased visibility and diagnostic capabilities within the overlay. The VXLAN header does not specify the protocol...
being encapsulated and therefore is currently limited to
encapsulating only Ethernet frame payload, nor does it provide the
ability to define OAM protocols. In addition, [RFC6335] requires
that new transports not use transport layer port numbers to identify
tunnel payload, rather it encourages encapsulations to use their own
identifiers for this purpose. VXLAN GPE is intended to extend the
existing VXLAN protocol to provide protocol typing, OAM, and
versioning capabilities.

The Version and OAM bits are introduced in Section 3, and the choice
of location for these fields is driven by minimizing the impact on
existing deployed hardware.

In order to facilitate deployments of VXLAN GPE with hardware
currently deployed to support VXLAN, changes from legacy VXLAN have
been kept to a minimum. Section 5 provides a detailed discussion
about how VXLAN GPE addresses the requirement for backward
compatibility with VXLAN.

2. VXLAN Without Protocol Extension

VXLAN provides a method of creating multi-tenant overlay networks by
encapsulating packets in IP/UDP along with a header containing a
network identifier which is used to isolate tenant traffic in each
overlay network from each other. This allows the overlay networks to
run over an existing IP network.

Through this encapsulation, VXLAN creates stateless tunnels between
VXLAN Tunnel End Points (VTEPs) which are responsible for adding/
removing the IP/UDP/VXLAN headers and providing tenant traffic
isolation based on the VXLAN Network Identifier (VNI). Tenant
systems are unaware that their networking service is being provided
by an overlay.

When encapsulating packets, a VTEP must know the IP address of the
proper remote VTEP at the far end of the tunnel that can deliver the
inner packet to the Tenant System corresponding to the inner
destination address. In the case of tenant multicast or broadcast,
the outer IP address may be an IP multicast group address, or the
VTEP may replicate the packet and send it to all known VTEPs. If
multicast is used in the underlay network to send encapsulated
packets to remote VTEPs, Any Source Multicast is used and each VTEP
serving a particular VNI must perform a (*, G) join to the same group
IP address.

Inner to outer address mapping can be determined in two ways. One is
source based learning in the data plane, and the other is
distribution via a control plane.
Source based learning requires a receiving VTEP to create an inner to outer address mapping by gleaning the information from the received packets by correlating the inner source address to the outer source IP address. When a mapping does not exist, a VTEP forwards the packets to all remote VTEPs participating in the VNI by using IP multicast in the IP underlay network. Each VTEP must be configured with the IP multicast address to use for each VNI. How this occurs is out of scope.

The control plane used to distribute inner to outer mappings is also out of scope. It could use a centralized authority or be distributed, or use a hybrid.

The VXLAN Network Identifier (VNI) provides scoping for the addresses in the header of the encapsulated PDU. If the encapsulated packet is an Ethernet frame, this means the Ethernet MAC addresses are only unique within a given VNI and may overlap with MAC addresses within a different VNI. If the encapsulated packet is an IP packet, this means the IP addresses are only unique within that VNI.

Figure 2: VXLAN GPE Header

Flags (8 bits): The first 8 bits of the header are the flag field. The bits designated "R" above are reserved flags. These MUST be set to zero on transmission and ignored on receipt.
Version (Ver): Indicates VXLAN GPE protocol version. The initial version is 0. If a receiver does not support the version indicated it MUST drop the packet.

Instance Bit (I bit): The I bit MUST be set to indicate a valid VNI.

Next Protocol Bit (P bit): The P bit is set to indicate that the Next Protocol field is present.

OAM Flag Bit (O bit): The O bit is set to indicate that the packet is an OAM packet.

Next Protocol: This 8 bit field indicates the protocol header immediately following the VXLAN GPE header.

VNI: This 24 bit field identifies the VXLAN overlay network the inner packet belongs to. Inner packets belonging to different VNIs cannot communicate with each other (unless explicitly allowed by policy).

Reserved: Reserved fields MUST be set to zero on transmission and ignored on receipt.

### 3.2. Multi Protocol Support

This draft defines the following two changes to the VXLAN header in order to support multi-protocol encapsulation:

P Bit: Flag bit 5 is defined as the Next Protocol bit. The P bit MUST be set to 1 to indicate the presence of the 8 bit next protocol field.

When UDP dest port=4790, P = 0 the "Next Protocol" field must be set to zero and the payload MUST be ETHERNET(L2) as defined by [RFC7348].

Flag bit 5 was chosen as the P bit because this flag bit is currently reserved in VXLAN.

Next Protocol Field: The lower 8 bits of the first word are used to carry a next protocol. This next protocol field contains the protocol of the encapsulated payload packet. A new protocol registry will be requested from IANA, see section 9.2.

This draft defines the following Next Protocol values:
0x1 : IPv4
0x2 : IPv6
0x3 : Ethernet
0x4 : Network Service Header [I-D.ietf-sfc-nsh]
0x5 : Multiprotocol Label Switching [RFC3031]. Please see [I-D.ietf-idr-tunnel-encaps] for more details.

3.3. OAM Support

Flag bit 7 is defined as the O bit. When the O bit is set to 1, the packet is an OAM packet and OAM processing MUST occur. Other header fields including Next Protocol MUST adhere to the definitions in Section 3. The OAM protocol details are out of scope for this document. As with the P-bit, bit 7 is currently a reserved flag in VXLAN.

3.4. Version Bits

VXLAN GPE bits 2 and 3 are defined as version bits. These bits are reserved in VXLAN. The version field is used to ensure backward compatibility going forward with future VXLAN GPE updates.

The initial version for VXLAN GPE is 0.

4. Outer Encapsulations

In addition to the VXLAN GPE header, the packet is further encapsulated in UDP and IP. Data centers based on Ethernet, will then send this IP packet over Ethernet.

Outer UDP Header:

Destination UDP Port: IANA has assigned the value 4790 for the VXLAN GPE UDP port. This well-known destination port is used when sending VXLAN GPE encapsulated packets.

Source UDP Port: The source UDP port is used as entropy for devices forwarding encapsulated packets across the underlay (ECMP for IP routers, or load splitting for link aggregation by bridges). Tenant traffic flows should all use the same source UDP port to lower the chances of packet reordering by the underlay for a given flow. It is recommended for VTEPs to generate this port number using a hash of the inner packet headers. Implementations MAY use the entire 16 bit source UDP port for entropy.
UDP Checksum: Source VTEPs MAY either calculate a valid checksum, or if this is not possible, set the checksum to zero. When calculating a checksum, it MUST be calculated across the entire packet (outer IP header, UDP header, VXLAN GPE header and payload packet). All receiving VTEPs must accept a checksum value of zero. If the receiving VTEP is capable of validating the checksum, it MAY validate a non-zero checksum and MUST discard the packet if the checksum is determined to be invalid.

Outer IP Header:

This is the header used by the underlay network to deliver packets between VTEPs. The destination IP address can be a unicast or a multicast IP address. The source IP address must be the source VTEP IP address which can be used to return tenant packets to the tenant system source address within the inner packet header.

When the outer IP header is IPv4, VTEPs MUST set the DF bit.

Outer Ethernet Header:

Most data centers networks are built on Ethernet. Assuming the outer IP packet is being sent across Ethernet, there will be an Ethernet header used to deliver the IP packet to the next hop, which could be the destination VTEP or be a router used to forward the IP packet towards the destination VTEP. If VLANs are in use within the data center, then this Ethernet header would also contain a VLAN tag.

The following figures show the entire stack of protocol headers that would be seen on an Ethernet link carrying encapsulated packets from a VTEP across the underlay network for both IPv4 and IPv6 based underlay networks.

| UDP Length                       |
| UDP Checksum                     |
```

VXLAN GPE Header:

```
+----------------------------------+-
|R|R|Ver|I|P|R|O|       Reserved                |
| VNI                              |
| Reserved                         |
```

4.1. Inner VLAN Tag Handling

If the inner packet (as indicated by the VXLAN GPE Next Protocol field) is an Ethernet frame, it is recommended that it does not contain a VLAN tag. In the most common scenarios, the tenant VLAN tag is translated into a VXLAN Network Identifier. In these scenarios, VTEPs should never send an inner Ethernet frame with a VLAN tag, and a VTEP performing decapsulation should discard any inner frames received with a VLAN tag. However, if the VTEPs are specifically configured to support it for a specific VXLAN Network Identifier, a VTEP may support transparent transport of the inner VLAN tag between all tenant systems on that VNI. The VTEP never looks at the value of the inner VLAN tag, but simply passes it across the underlay.

4.2. Fragmentation Considerations

VTEPs MUST never fragment an encapsulated VXLAN GPE packet, and when the outer IP header is IPv4, VTEPs MUST set the DF bit in the outer IPv4 header. It is recommended that the underlay network be configured to carry an MTU at least large enough to accommodate the added encapsulation headers. It is recommended that VTEPs perform Path MTU discovery [RFC1191] [RFC1981] to determine if the underlay network can carry the encapsulated payload packet.

5. Backward Compatibility

5.1. VXLAN VTEP to VXLAN GPE VTEP

A VXLAN VTEP conforms to VXLAN frame format and uses UDP destination port 4789 when sending traffic to VXLAN GPE VTEP. As per VXLAN, reserved bits 5 and 7, VXLAN GPE P and O-bits respectively must be
set to zero. The remaining reserved bits must be zero, including the
VXLAN GPE version field, bits 2 and 3. The encapsulated payload MUST
be Ethernet.

5.2. VXLAN GPE VTEP to VXLAN VTEP

A VXLAN GPE VTEP MUST NOT encapsulate non-Ethernet frames to a VXLAN
VTEP. When encapsulating Ethernet frames to a VXLAN VTEP, the VXLAN
GPE VTEP MUST conform to VXLAN frame format and hence will set the P
bit to 0, the Next Protocol to 0 and use UDP destination port 4789.
A VXLAN GPE VTEP MUST also set O = 0 and Ver = 0 when encapsulating
Ethernet frames to VXLAN VTEP. The receiving VXLAN VTEP will treat
this packet as a VXLAN packet.

A method for determining the capabilities of a VXLAN VTEP (GPE or
non-GPE) is out of the scope of this draft.

5.3. VXLAN GPE UDP Ports

VXLAN GPE uses a IANA assigned UDP destination port, 4790, when
sending traffic to VXLAN GPE VTEPs.

5.4. VXLAN GPE and Encapsulated IP Header Fields

When encapsulating and decapsulating IPv4 and IPv6 packets, certain
fields, such as IPv4 Time to Live (TTL) from the inner IP header need
to be considered. VXLAN GPE IP encapsulation and decapsulation
utilizes the techniques described in [RFC6830], section 5.3.

6. VXLAN GPE Examples

This section provides three examples of protocols encapsulated using
the Generic Protocol Extension for VXLAN described in this document.

\begin{verbatim}
0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-
|R|R|0|0|I|1|R|0|       Reserved                |    NP = IPv4  |
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-
|                VXLAN Network Identifier (VNI) |   Reserved    |
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-
|               Original IPv4 Packet                |
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-
\end{verbatim}

\textbf{Figure 5: IPv4 and VXLAN GPE}
7. Security Considerations

VXLAN’s security is focused on issues around L2 encapsulation into L3. With VXLAN GPE, issues such as spoofing, flooding, and traffic redirection are dependent on the particular protocol payload encapsulated.

8. Contributors
9. Acknowledgments

A special thank you goes to Dino Farinacci for his guidance and detailed review.

10. IANA Considerations

10.1. UDP Port

UDP 4790 port has been assigned by IANA for VXLAN GPE.
10.2. VXLAN GPE Next Protocol

IANA is requested to set up a registry of "Next Protocol". These are 8-bit values. Next Protocol values 0, 1, 2, 3 and 4 are defined in this draft. New values are assigned via Standards Action [RFC5226].

+-----------------+----------+-----------------+
| Next Protocol   | Description | Reference       |
+-----------------+----------+-----------------+
| 0               | Reserved  | This Document   |
| 1               | IPv4     | This Document   |
| 2               | IPv6     | This Document   |
| 3               | Ethernet | This Document   |
| 4               | NSH      | This Document   |
| 5               | MPLS     | This Document   |
| 6..253          | Unassigned |                |
+-----------------+----------+-----------------+

10.3. VXLAN GPE Flag and Reserved Bits

There are ten flag bits at the beginning of the VXLAN GPE header, followed by 16 reserved bits and an 8-bit reserved field at the end of the header. New bits are assigned via Standards Action [RFC5226].

Bits 0-1 - Reserved

Bits 2-3 - Version

Bit 4 - Instance ID (I bit)

Bit 5 - Next Protocol (P bit)

Bit 6 - Reserved

Bit 7 - OAM (O bit)

Bit 8-23 - Reserved

Bits 24-31 in the 2nd Word -- Reserved

Reserved bits/fields MUST be set to 0 by the sender and ignored by the receiver.
