Abstract

The framework for preparation and comparison of internationalized strings ("PRECIS") defines several classes of strings for preparation and comparison. Case mapping is defined because many protocols perform case-sensitive or case-insensitive string comparison and so preparation of the string is mandatory. The Internationalized Domain Names in Applications (IDNA) and the PRECIS problem statement describes mappings for internationalized strings that are not limited to case, but include width mapping and mapping of delimiters and other specials that can be taken into consideration. This document provides guidelines for authors of protocol profiles of the PRECIS framework and describes several mappings that can be applied between receiving user input and passing permitted code points to internationalized protocols. The mappings described here are expected to be applied as an additional mapping and locale-/context-dependent case mapping.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at http://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on November 7, 2015.
1. Introduction

In many cases, user input of internationalized strings is generated through the use of an input method editor ("IME") or through copy-and-paste from free text. Users generally do not care about the case and/or width of input characters because they consider those characters to be functionally equivalent or visually identical. Furthermore, users rarely switch the IME state to input special characters such as protocol elements. For Internationalized Domain Names ("IDNs"), the IDNA Mapping specification [RFC5895] describes methods for handling these issues. For PRECIS strings, case mapping and width mapping are defined in the PRECIS framework specification [I-D.ietf-precis-framework]. Further, the handling of mappings other than case and width, such as delimiter, special, and local case, are also important in order to increase the probability that the resulting strings compare as users expect. This document provides guidelines for authors of protocol profiles of the PRECIS framework and describes several mappings that can be applied between receiving user input and passing permitted code points to internationalized protocols. The delimiter mapping and special mapping rules described here are applied as "additional mappings" beyond those defined in the PRECIS framework, whereas the "local case mapping" rule provides locale-dependent and context-dependent alternative case mappings for specific target characters.

2. Protocol dependent mappings

The PRECIS framework defines several protocol-independent mappings. The additional mappings and local case mapping defined in this document are protocol-dependent, i.e., they depend on the rules for a particular application protocol.

2.1. Delimiter mapping

Some application protocols define delimiters for their own use, resulting in the fact that the delimiters are different for each protocol. The delimiter mapping table should therefore be based on a well-defined mapping table for each protocol.

Delimiter mapping is used to map characters that are similar to protocol delimiters into the canonical delimiter characters. For example, there are width-compatible characters that correspond to the '0' in email addresses and the ':' and '/' in URIs. The '+', '-', '<' and '>' characters are other common delimiters that might require such mapping. For the FULL STOP character (U+002E), a delimiter in the visual presentation of domain names, some IMEs produce a character such as IDEOGRAPHIC FULL STOP (U+3002) when a user types FULL STOP on the keyboard. In all these cases, the visually similar
characters that can come from user input need to be mapped to the correct protocol delimiter characters before the string is passed to the protocol.

2.2. Special mapping

Aside from delimiter characters, certain protocols have characters which need to be mapped in ways that are different from the rules specified in the PRECIS framework (e.g., mapping non-ASCII space characters to ASCII space). In this document, these mappings are called "special mappings". They are different for each protocol. Therefore, the special mapping table should be based on a well-defined mapping table for each protocol. Examples of special mapping are the following;

- White spaces are mapped to SPACE (U+0020)
- Some characters such as control characters are mapped to nothing (Deletion)

As examples, EAP [RFC3748], SASLprep [RFC4013], IMAP4 ACL [RFC4314] and LDAPprep [RFC4518] define the rule that some codepoints for the non-ASCII space are mapped to SPACE (U+0020).

2.3. Local case mapping

The purpose of local case mapping is to increase the probability of results that users expect when character case is changed (e.g., map uppercase to lowercase) between input and use in a protocol. Local case mapping selectively affects characters whose case mapping depends on locale and/or context.

As an example of locale and context-dependent mapping, LATIN CAPITAL LETTER I ("I", U+0049) is normally mapped to LATIN SMALL LETTER I ("i", U+0069); however, if the case of Turkish (or one of several other languages), unless an I is before a dot_above, the character should be mapped to LATIN SMALL LETTER DOTLESS I (U+0131).

Case mapping using Unicode Default Case Folding in PRECIS framework does not consider such locale or context because it is a common framework for internationalization. Local case mapping defined in this document corresponds to demands from applications which supports users’ locale and/or context. The complete set of possible target characters for local case mapping are the characters specified in the SpecialCasing.txt [Specialcasing] file in section 3.13 of the Unicode Standard [Unicode], but the specific set of target characters selected for local case mapping depends on locale and/or context, as further explained in the SpecialCasing.txt file.
The case folding method for a selected target character is to map into lower case as defined in SpecialCasing.txt. The case folding method for all other, non-target characters is as specified in Section 4.1.3 of the PRECIS framework (i.e., it is RECOMMENDED to use Unicode Default Case Folding for all non-target characters). When an application supports users’ locale and/or context, use of local case mapping can increase the probability that string comparisons yield the results that users expect.

If Unicode Default Case Folding is selected as "Case Mapping" in PRECIS profiles registry, PRECIS profile designers may consider whether local case mapping can be applied. And if it can be applied, it is better to add "local case mapping is applicable alternatively" after "Unicode Default Case Folding" for note to application developers. The reason why local case mapping is alternative to Unicode Default Case Folding is written in the Appendix B.

3. Order of operations

Delimiter mapping and special mapping described in this document are expected to be applied as additional mappings in the PRECIS framework. The mappings described in this document could be applied in any order. This section specifies a particular order to minimize the effect of codepoint changes introduced by the mappings. This mapping order is very general and has been designed to be acceptable to the widest user community.

1. Delimiter mapping
2. Special mapping

4. Security Considerations

As well as Mapping Characters for IDNA2008 [RFC5895], this document suggests creating mappings that might cause confusion for some users while alleviating confusion in other users. Such confusion is not covered in any depth in this document.

5. IANA Considerations

This document has no actions for the IANA.

6. Acknowledgment

Martin Duerst suggested a need for the case folding about the mapping (map final sigma to sigma, German sz to ss,.).

Appendix A. Mapping type list each protocol

A.1. Mapping type list for each protocol

This table is the mapping type list for each protocol. Values marked "o" indicate that the protocol use the type of mapping. Values marked "-" indicate that the protocol doesn’t use the type of mapping.

**Appendix B.** The reason why local case mapping is alternative to case mapping in PRECIS framework

One outstanding issue regarding full case folding for characters is, the character "LATIN SMALL LETTER SHARP S" (U+00DF) (hereinafter referred to as "eszett") becomes two "LATIN SMALL LETTER S"s (U+0073 U+0073) by performing the case mapping using Unicode Default Case Folding in the PRECIS framework. On the other hand, eszett doesn’t become a different codepoint by performing the case mapping in SpecialCasing.txt. If local case mapping in this document is not an alternative to case mapping in PRECIS framework, PRECIS profile designers can select both mappings, therefore, German’s eszett can not keep the locale if the case mapping in the PRECIS framework was performed after the local case mapping.

**Appendix C.** Limitation to local case mapping

As described in section Section 2.3, the possible target characters of local case mapping are specified in SpecialCasing.txt. The Unicode Standard (at least, up to version 7.0.0) does not define any context-dependent mappings between "GREEK SMALL LETTER SIGMA" (U+03C3) (hereinafter referred to as "small sigma") and "GREEK SMALL LETTER FINAL SIGMA" (U+03C2) (hereinafter referred to as "final sigma"). Thus, local case mapping is not applicable to small sigma or final sigma, so case mapping in the PRECIS framework always maps final sigma to small sigma, independent of context, as specified by Unicode Default Case Folding. (Note: Following comments are from SpecialCasing.txt.)

```
# Note: the following cases are not included, since they would case-fold in lowercasing
# 03C3; 03C2; 03A3; 03A3; Final_Sigma; # GREEK SMALL LETTER SIGMA
# 03C2; 03C3; 03A3; 03A3; Not_Final_Sigma; # GREEK SMALL LETTER
```
Local case mapping follows Unicode definition, so mapping of small sigma and final sigma is up to the definition.

Appendix D. Change Log

D.1. Changes since -00

- Modify the Section 4.3 "Local case mapping" to specify the method to calculate codepoints that local case mapping targets.

- Add the Section 6 "Open issues".

- Modify the Section 7 "IANA Considerations".

- Modify the Section 8 "Security Considerations".

- Remove the "The initial PRECIS local case mapping registrations".

- Add the Appendix C "Code points list for local case mapping".

- Add the Appendix D "Change Log".

D.2. Changes since -01

- Unified PRECIS notation in all capital letters as well as other documents.

- Removed the Section 1 "Types of mapping" and the Section 2 "Protocol independent mapping" because width mapping is now in framework document.

- Added relationship between the framework document and this document in the Section 3 "Order of operations".

- Updated the Section 4 "Open issues" to address new issue raised on mailing list.

- Move the Section 6 "IANA Considerations" after the Section 5 "Security Considerations".

- Remove the Appendix B "Codepoints which need special mapping" and mentioned related documents in the Section 2.2.

D.3. Changes since -02

- Removed the "Open issues".
D.4. Changes since -03

- Modify the Section 1 "Introduction" in more clear text.
- Modify the Section 2.3 "Local case mapping" to clarify the purpose of the local case mapping and an example, and add restriction to use with PRECIS framework.
- Change the format in the Appendix B "Code points list for local case mapping".
- Split the Section 7 "References" into "Normative References" and "Informative References".
- Update the Unicode version 6.2 to 6.3 in this document.

D.5. Changes since -04

- Correct a sentence in the Section 2.3 "Local case mapping".

D.6. Changes since -05

- Correct some sentences in this document.
- Modify the local case mapping’s rule and target characters in Section 2.3 "Local case mapping". This is to avoid user’s confusion towards Greek’s final sigma and German’s eszett.
- Add the Section 4 "Open issues".
- Modify the Section 8 "Security Considerations".
- Modify the table format in the Appendix A. "Mapping type list each protocol".
- Removed the Appendix B "Code points list for local case mapping".
- Add the Appendix B "Local case mapping vs Case mapping".

D.7. Changes since -06

- Removed the Section 4 "Open issues".
- Change the title of the Appendix B "Local case mapping vs Case mapping" to "The reason why local case mapping is alternative to case mapping in PRECIS framework".
- Add the Appendix C "Limitation to local case mapping".
D.8. Changes since -07
   o Modify the Section 1 "Introduction".
   o Modify the local case mapping’s rule and target characters in Section 2.3 "Local case mapping".
   o Modify the Section 3 "Order of operations".

D.9. Changes since -08
   o Updated the Unicode version 6.3 to 7.0 in this document.

D.10. Changes since -09
   o Modify the Section 1 "Introduction" to clarify to the discussion of string matching and the use of mappings from the SpecialCasing.txt.
   o Modify the Section 2.3 "Local case mapping" to clarify to the discussion of string matching and the use of mappings from the SpecialCasing.txt.
   o Modify the Appendix B "The reason why local case mapping is alternative to case mapping in PRECIS framework" to state the result of the case mapping in SpecialCasing.txt of eszett.
   o Clarify the Appendix C "Limitation to local case mapping".
