Definition of Managed Objects for Synthetic Sources for Performance Monitoring Algorithms.

<draft-ietf-rmonmib-sspm-mib-12.txt>

Status of this Memo

This document is an Internet-Draft and is in full conformance with all provisions of Section 10 of RFC2026. Internet-Drafts are working documents of the Internet Engineering Task Force (IETF), its areas, and its working groups. Note that other groups may also distribute working documents as Internet-Drafts.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

To view the list Internet-Draft Shadow Directories, see http://www.ietf.org/shadow.html.

Abstract

This memo defines a portion of the Management Information Base (MIB) for use with network management protocols in the Internet community. In particular, it describes objects for configuring Synthetic Sources for Performance Monitoring (SSPM) algorithms.

Distribution of this memo is unlimited.

1. Introduction

This memo defines a portion of the Management Information Base (MIB) for use with network management protocols in the Internet community.
In particular, it defines a method of describing Synthetic Sources for Performance Monitoring (SSPM). This is useful within the RMON framework [RFC3577] for performance monitoring in the cases where it is desirable to inject packets into the network for the purpose of monitoring their performance with the other MIBs in that framework.

This memo also includes a MIB module.

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC 2119 [RFC2119].

2. The Internet-Standard Management Framework

For a detailed overview of the documents that describe the current Internet-Standard Management Framework, please refer to section 7 of RFC 3410 [RFC3410].

Managed objects are accessed via a virtual information store, termed the Management Information Base or MIB. MIB objects are generally accessed through the Simple Network Management Protocol (SNMP). Objects in the MIB are defined using the mechanisms defined in the Structure of Management Information (SMI). This memo specifies a MIB module that is compliant to the SMIv2, which is described in STD 58, RFC 2578 [RFC2578], STD 58, RFC 2579 [RFC2579] and STD 58, RFC 2580 [RFC2580].

3. Overview

This document defines a MIB module for the purpose of remotely controlling synthetic sources (or 'active' probes) and sinks for the purpose of enhancing remote performance monitoring capabilities within IP networks and services. Much work within the IETF exists related to performance monitoring. One interesting aspect of this body of work is that it does not explicitly define an 'active' probe capability. An active probe capability is complimentary to existing capabilities, and this MIB module is developed to fill this void.

3.1 Terms

The following definitions apply throughout this document:

- 'Performance monitoring' is the act of monitoring traffic for the purpose of evaluating a statistic of a metric related to the performance of the system. A performance monitoring system is comprised of a) traffic generators, b) measurement, c) data reduction, and d) reporting. The traffic generators may be natural sources, synthetic sources or intrusive sources.
A 'synthetic source' is a device or an embedded software program which generates a data packet (or packets) and injects it (them) onto the path to a corresponding probe or existing server solely in support of a performance monitoring function. A synthetic source may talk intrusively to existing application servers.

The design goals for this MIB module are:

- Compliment the overall performance management architecture being defined within the RMONMIB WG, refer to the RMONMIB framework document [RFC3577]. This MIB module is defined within the context of the APM-MIB [RFC3729].

- Extensibility - the MIB module should be easily extended to include a greater set of protocols and applications for performance monitoring purposes.

- Flexible - it should support both round trip and one way measurements.

- Security - the control of the source and sink of traffic is handled by a management application and communication is recommended via SNMPv3.

This document is organized as follows. The next section discusses the relationship of this MIB module to other MIB modules from the RMONMIB and DISMAN working groups. Then the structure of the MIB module is discussed. Finally, the MIB module definitions are given.

4. Relationship to Other MIB modules

This MIB module is designed to be used in conjunction with the RMON MIB Working Groups two other MIB modules for application performance measurement: Application Performance Measurement MIB [RFC3729] and Transport Performance Metrics MIB [RFCXXX2]. These MIB modules define reporting capabilities for that framework. The intent of this MIB module is to define a method for injecting packets into the network utilizing probe capabilities defined in the base MIB modules and measured with the reporting MIB modules. Other reporting MIB modules may be used as well.

Specifically, this MIB module uses the AppLocalIndex as defined in the APM-MIB to map measurement configuration information to definition and reporting structures defined in the APM-MIB.

5. Relationship to Other Work

Much work has already occurred within the IETF which has a direct
bearing on the development of active performance probe definitions. This body of work is addressed in various working groups over the years. In this section we focus our attention to the work of a) the IPPM working group, b) the DISMAN working group, c) the RMON working group, d) the ApplMIB working group, and e) the RTFM working group.

5.1 IPPM

The IPPM working group has defined in detail a set of performance metrics, sampling techniques and associated statistics for transport-level, or connectivity-level, measurements. The IPPM framework document [RFC2330] discusses numerous issues around sampling techniques, clock accuracy, resolution and skew, wire time versus host time, error analysis, etc. Much of these are considerations for Configuration and Implementation Issues discussed below. The IPPM working group has defined several metrics and their associated statistics, including

+ a connectivity metric [RFC2678]
+ one-way delay metric [RFC2679]
+ one-way loss metric [RFC2680]
+ round trip delay and loss metrics [RFC2681]
+ delay variation metric [RFC3393]
+ a streaming media metric [RFC3432]
+ a throughput metric [EBT] and [TBT], and
+ others are under development.

These (or a subset) could form the basis for a set of active, connectivity-level, probe types designed for the purpose of monitoring the quality of transport services. A consideration of some of these metrics may form a set of work activities and a set of early deliverables out of a group developing an active probe capability.

During the early development of the SSPM-MIB, it became apparent that a one-way measurement protocol was required in order for the SSPM-MIB to control a one-way measurement. This led to the current work with the IPPM WG on the development of the One-Way Measurement Protocol (OWDP) [ODP]. This protocol work includes both the measurement protocol itself, as well as the development of a separate control protocol. This later control protocol is redundant with the current
work on the SSPM-MIB. The SSPM-MIB could be used as an alternative to the one-way delay control protocol.

5.2 DISMAN

The DISMAN working group has defined a set of ‘active’ tools for remote management. Of relevance to this draft are:

+ the pingMIB [RFC2925],
+ the DNS Lookup MIB [RFC2925],
+ the tracerouteMIB [RFC2925],
+ the scriptMIB [RFC3165], and
+ the expressionMIB [RFC2982].

The pingMIB and tracerouteMIB define an active probe capability, primarily for the remote determination of path and path connectivity. There are some performance related metrics collected from the pingMIB and one could conceivably use these measurements for the evaluation of a limited set of performance statistics. But there is a fundamental difference in determining connectivity versus determining the quality of that connectivity. However, in the context of performance monitoring, a fault can be viewed as not performing at all. Therefore, they should both be monitored with the same probes to reduce network traffic.

The DNS Lookup MIB also includes some probe-like capabilities and performance time measurements for the DNS lookup. This could be used to suggest details of a related session-level, active probe.

The scriptMIB allows a network management application to distribute and manage scripts to remote devices. Conceivably, these scripts could be designed to run a set of active probe monitors on remote devices.

5.3 RMON

The RMON working group has developed an extensive, passive monitoring capability defined in RFC 2819 [RFC2819] and RFC 2021 [RFC2021] as well as additional MIB modules. Initially, the monitors collected statistics at the MAC layer, but has now been extended to higher-layer statistics. Higher-layer statistics are identified through the definition of a Protocol Directory [RFC2021]. See the RMONMIB framework document [RFC3577] for an overview of the RMONMIB capabilities.
Within this context, the development of an active traffic source for performance monitoring fits well within the overall performance monitoring architecture being defined within the RMON WG.

5.4 ApplMIB

The ApplMIB working group defined a series of MIB modules which monitor various aspects of applications, processes and services.

The System Application MIB [RFC2287] describes a basic set of managed objects for fault, configuration and performance management of applications from a systems perspective. More specifically, the managed objects it defines are restricted to information that can be determined from the system itself and which does not require special instrumentation within the applications to make the information available.

The Application MIB [RFC2564] complements the System Application MIB, providing for the management of applications’ common attributes which could not typically be observed without the cooperation of the software being managed. There are attributes which provide information on application and communication performance.

The WWW MIB [RFC2594] describes a set of objects for managing networked services in the Internet Community, particularly World Wide Web (WWW) services. Performance attributes are available for the information about each WWW service, each type of request, each type of response and top accessed documents.

In the development of synthetic application-level probes, consideration should be given to the relationship of the application MIB modules to the measurements being performed through a synthetic application-level probe. Similar, cross-indexing issues arise within the context of the RMON monitoring and synthetic application-level active probes.

5.5 SNMPCONFIG

The SNMPCONFIG working group has created an informational RFC 3512 [RFC3512] which outlines the most effective methods for using the SNMP Framework to accomplish configuration management. This work includes recommendations for device specific as well as network-wide (Policy) configuration. The group is also chartered to write any MIB modules necessary to facilitate configuration management, specifically they will write a MIB module which describes a network entities capabilities and capacities which can be used by management entities making policy decisions at a network level or device specific level.
Currently the SNMPCONF working group is focused on the SNMP Configuration MIB for policy [PMM]. It is conceivable that one would want to monitor the performance of newly configured policies as they are implemented within networks. This would require correlation of the implemented policy and a related performance monitoring policy, which would specify synthetic probe definitions. For synthetic probes there would be a need to have configuration of a) a single probe, b) several probes, c) source and destination probes and d) intermediate probes. In addition, it may be necessary to configure any or all of these combinations simultaneously. It is hoped that the work of SNMPCONF will suffice. The scripting language defined by the SNMP Configuration MIB could allow for active monitoring to be activated and configured from a policy management script. Further, the results of active monitoring could become arguments in further policy decisions. This notion is reflected in the decision flow outlined in Figure 1 below.

5.6 RTFM

The Realtime Traffic Flow Measurement (RTFM) working group is concerned with issues relating to traffic flow measurements, usage reporting for network traffic and Internet accounting. Various documents exist which describe requirements [RFC1272], traffic flow measurement architectures [RFC2722], and a traffic flow MIB [RFC2720]. The work in this group is focused on passive measurements of user traffic. As such, its work is related to the monitoring work within the RMON WG. Fundamentally, their attention has not been concerned with methods of active traffic generation.
5.7 Relationship to Other Work: Summary

In summary, the development of an active traffic generation capability primarily for the purpose of performance monitoring should draw upon various activities, both past and present within the IETF. Figure 1 shows the relationship of the various work activities briefly touched upon in this section.

Horizontally, across the top of the figure are overall control functions, which would coordinate the various aspects of the performance monitoring systems. Vertically at the bottom of the figure are the functions which comprise the minimum performance monitoring capability, i.e., traffic generation, monitoring and measurements, and data reduction. Traffic generation is address in this MIB module. Monitoring and measurement is address in the APM-MIB [RFC3729] and the TPM-MIB [RFCXXX2] modules. Data reduction is not yet addressed within the IETF. But data reduction could include both spatial and temporal aggregations and at different levels of reduction. This is indicated in the figure by the arrow labeled "Various levels and span".
Figure 1: Coverage for an overall performance monitoring system

6. MIB Structure

This section presents the structure of the MIB module. The objects are arranged into the following groups:

- general information
- source configuration
- sink configuration
6.1. General Information
This section provides general information about the capabilities of
the probe. Currently this information is related to the resolution of
the probe clock and its source.

6.2. Source Configuration
The source is configured with a pair of tables. The first,
sspmSourceProfileTable, defines a set of profiles for monitoring.
These profiles are then used by the second table,
sspmSourceControlTable, to instantiate a specific measurement. This
MIB module takes an IP centric view of the configuration of the
measurement.

6.3. Sink Configuration
Configures the sink for measurements. If the test is round-trip then
this table is on the same probe as the source configuration. If the
test is one-way then the table is on a different probe. The
sspmSinkInstance is a unique identifier for the entry per probe.
Additional attributes are provided for test type and source of the
test to uniquely identifier entries in the table.

SYNTAX      AppLocalIndex
MAX-ACCESS  read-create
STATUS      current
DESCRIPTION
 "The AppLocalIndex value which uniquely identifies the
measurement per the APM-MIB. In order to create a row
in this table there must be a corresponding row in the
sspmCapabilitiesTable.

When attempting to set this object, if there exists
no corresponding row in the sspmCapabilitiesTable,
then the agent should return a 'badValue' error."
 ::= { sspmSourceProfileEntry 2 }

sspmSourceProfilePacketSize OBJECT-TYPE
SYNTAX      Unsigned32
MAX-ACCESS  read-create
STATUS      current
DESCRIPTION
 "The size of packet to be transmitted in bytes. The
size accounts for all data within the IPv4 or IPv6
payloads, excluding the IP headers, IP header options
and link-level protocol headers.

If the size is set smaller than the minimum allowed
packet size or greater than the allowed maximum
packet size then the set should fail and the agent
should return a 'badValue' error."
 ::= { sspmSourceProfileEntry 3 }

sspmSourceProfilePacketFillType OBJECT-TYPE
SYNTAX      INTEGER {
            random (1),
            pattern (2),
            url(3)
          }
MAX-ACCESS  read-create
STATUS      current
DESCRIPTION
"Indicates how the packet is filled.

'random' indicates that the packet contains random data patterns. This is probe and implementation dependent.

'pattern' indicates that the pattern defined in the sspmSourceProfilePacketFillValue attribute is used to fill the packet.

'url' indicates that the value of sspmSourceProfilePacketFillValue should contain a URL. The contents of the document at that URL are retrieved when sspmSourceStatus becomes active and utilized in the packet. If the attempt to access that URL fails then the row status is set to 'notReady' and the set should fail with 'inconsistentValue'. This value must contain a dereferencable URL of the type 'http:', https:' or 'ftp:' only."

::= { sspmSourceProfileEntry 4 }

sspmSourceProfilePacketFillValue OBJECT-TYPE
SYNTAX OCTET STRING (SIZE(0..255))
MAX-ACCESS read-create
STATUS current
DESCRIPTION
"The string value to fill the packet with. If sspmSourceProfilePacketFillType is set to 'pattern' then this pattern is repeated until the packet is sspmSourcePacketSize in bytes. Note that if length of the octet string specified for this value does not divide evenly into the packet size then an incomplete last copy of this data may be copied into the packet. If the value of sspmSourceProfilePacketFillType is set to 'random' then this attribute is unused. If the value of the sspmSourceProfilePacketFillType is set to 'url' then the URL specified in this attribute is retrieved and used by the probe. In case of a URL, this value must contain a dereferencable URL of the type 'http:', https:' or 'ftp:' only."

::= { sspmSourceProfileEntry 5 }

sspmSourceProfileTOS OBJECT-TYPE

MAX-ACCESS    read-create
STATUS        current
DESCRIPTION
"This object is used to specify the Flow Label in a IPv6 packet (RFC 2460) to force special handling by the IPv6 routers, e.g., non-default quality-of-service handling. This object is meaningful only when the object sspmSourceDestAddressType is IPv6(2). The value of this object defaults to zero if not set."
DEFVAL { 0 }
::= { sspmSourceProfileEntry 7 }

sspmSourceProfileLooseSrcRteFill OBJECT-TYPE
SYNTAX        OCTET STRING (SIZE(0..240))
MAX-ACCESS    read-create
STATUS        current
DESCRIPTION
"In the event that the test should run over a specific route. Intent is to force the route using the Loose Source Route option in IPv4 [RFC791] and IPv6 [RFC2460]. This object contains a series of IP addresses along the path that would be put into the loose source route option in the IP header. The IPv4 addresses are to be listed as 32-bit address values and the IPv6 addresses are to be listed as a string of 128-bit addresses. The maximum length allowed within the IPv4 source route option is 63 addresses. To simply account for IPv6 addresses as well, the maximum length of the octet string is 240. This allows for up to 60 IPv4 addresses or up to 15 IPv6 addresses in the string."
::= { sspmSourceProfileEntry 8 }

sspmSourceProfileLooseSrcRteLen OBJECT-TYPE
SYNTAX        Integer32(0..240)
MAX-ACCESS read-create
STATUS current
DESCRIPTION
"In the event that the test should run over a specific route. Intent is to force the route. This attribute specifies the length of data to be copied from the sspmSourceProfileLooseSrcRteFill into the route data fields of the loose source route options in the IPv4 or IPv6 headers."
::= { sspmSourceProfileEntry 9 }

sspmSourceProfileTTL OBJECT-TYPE
SYNTAX Integer32(1..255)
MAX-ACCESS read-create
STATUS current
DESCRIPTION
"If non-zero specifies the value to place into the TTL field on transmission."

10. Intellectual Property

The IETF takes no position regarding the validity or scope of any intellectual property or other rights that might be claimed to pertain to the implementation or use of the technology described in this document or the extent to which any license under such rights...
might or might not be available; neither does it represent that it has made any effort to identify any such rights. Information on the IETF’s procedures with respect to rights in standards-track and standards-related documentation can be found in BCP-11. Copies of claims of rights made available for publication and any assurances of licenses to be made available, or the result of an attempt made to obtain a general license or permission for the use of such proprietary rights by implementors or users of this specification can be obtained from the IETF Secretariat.

The IETF invites any interested party to bring to its attention any copyrights, patents or patent applications, or other proprietary rights which may cover technology that may be required to practice this standard. Please address the information to the IETF Executive Director.

11. Security Considerations

This MIB module defines objects to allow packets to be injected into the network for the purpose of measuring some performance characteristics. As such, the MIB module may contain sensitive network and application data, e.g., user IDs and passwords. Further, if security is compromised, this MIB module could provide a source for denial-of-service, and potential other, attacks. These issues will be addressed within this section.

There are a number of management objects defined in this MIB module that have a MAX-ACCESS clause of read-write and/or read-create. Such objects may be considered sensitive or vulnerable in some network environments. The support for SET operations in a non-secure environment without proper protection can have a negative effect on network operations. These are the tables and objects and their sensitivity/vulnerability:

+ The sspmSourceProfileTable contains objects that configure link-level, IP and application level data used within test suites. These objects with a MAX-ACCESS clause of read-write and/or read-create are:

  - sspmSourcePacketSize - configures the overall size of the test packets,
  - sspmSourceProfileTOS - sets the TOS field in the IPv4 and IPv6 headers,
  - sspmSourceProfileLooseSrcRteFill and sspmSourceProfileLooseSrcRteLen - gives a list of IPv4 or IPv6 addresses for the loose source route options in the IP headers,
o sspmSourceProfileFlowLabel - sets the Flow Label in the IPv6 header,

o sspmSourceProfileTTL - sets the TTL field in the packet headers,

o sspmSourceProfileNoFrag - sets the No Fragment bit in the packet headers,

o sspmSourceProfile8021Tagging - sets the Tag field in the 802.1 headers, and

o sspmSourceProfileUsername and sspmSourceProfilePassword - these hold the ID and passwords specific to an application test profile.

+ The sspmSourceControlTable contains objects that configure IP and application level data used within a given test. These objects with a MAX-ACCESS clause of read-write and/or read-create are:

  o sspmSourceControlSrc - controls the source IP address used on the test packets,

  o sspmSourceControlDestAddr - holds the destination address for the specific test packet,

  o sspmSourceControlTimeout, sspmSourceControlSamplingDist and sspmSourceControlFrequency - control the nature and frequency of the test packet injection onto the network, and

  o sspmSourceControlFirstSeqNum and sspmSourceControlLastSeqNum - sets the first and last sequence numbers for the specific test.

+ The sspmSinkTable contains objects that configure the recipient of the test packets. As such, the objects in this table have no security issues related to them.

There are some attributes which configure username and password information for some application level protocols as indicated above. Access to these attributes may provide unauthorized use of resources. These attributes are: sspmSourceProfileUsername and sspmSourceProfilePassword.

There are some attributes which configure the size and rate of traffic flows for the purpose of performance measurements. Access to these attributes may exacerbate the use of this MIB module in denial-
of-service attacks. It is possible to define a maximum packet rate on the device and indicate this maximum rate through the sspmSourceFrequency object. This object reflects the maximum acceptable packet rate that a device supporting this MIB module is willing to generate. This places a bound on setting the test packet rate through the sspmSourceControlFrequency object. Other objects which control aspects of the test packets related to packet size and rate are the sspmSourceControlTimeOut, sspmSourceControlSamplingDist and sspmSourceControlFrequency.

The objects sspmSourceControlSrc, sspmSourceControlDestAddr, sspmSourceControlLooseSrcRteFill and sspmSourceControlLooseSrcRteLen control the setting of the source and destination addresses on the packet headers and the routing of the packets. The device should not allow the setting of source addresses on the test packets other than those which are administratively configured onto the device. This is controlled by using the syntax InterfaceIndexOrZero for the control of the source address through the sspmSourceControlSrc object.

It is thus important to control even GET access to these objects and possibly to even encrypt the values of these object when sending them over the network via SNMP. Not all versions of SNMP provide features for such a secure environment.

SNMP versions prior to SNMPv3 did not include adequate security. Even if the network itself is secure (for example by using IPSec), even then, there is no control as to who on the secure network is allowed to access and GET/SET (read/change/create/delete) the objects in this MIB module.

It is RECOMMENDED that implementers consider the security features as provided by the SNMPv3 framework (see [RFC3410], section 8), including full support for the SNMPv3 cryptographic mechanisms (for authentication and privacy).

Further, deployment of SNMP versions prior to SNMPv3 is NOT RECOMMENDED. Instead, it is RECOMMENDED to deploy SNMPv3 and to enable cryptographic security. It is then a customer/operator responsibility to ensure that the SNMP entity giving access to an instance of this MIB module is properly configured to give access to the objects only to those principals (users) that have legitimate rights to indeed GET or SET (change/create/delete) them.
