A YANG Data Model for Routing Information Protocol (RIP)
draft-ietf-rtgwg-yang-rip-08

Abstract

This document describes a data model for the management of the Routing Information Protocol (RIP). Both RIP version 2 and RIPng are covered. The data model includes definitions for configuration, operational state, and Remote Procedure Calls (RPCs).

The YANG model in this document conforms to the Network Management Datastore Architecture (NMDA).

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at http://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on July 14, 2018.

This document is subject to BCP 78 and the IETF Trust’s Legal Provisions Relating to IETF Documents (http://trustee.ietf.org/license-info) in effect on the date of publication of this document. Please review these documents.
1. Introduction

This document introduces a YANG [RFC7950] data model for the Routing Information Protocol (RIP) [RFC2453][RFC2080]. RIP was designed to work as an Interior Gateway Protocol (IGP) in moderate-size Autonomous Systems (AS).

This YANG model supports both RIP version 2 and RIPng. RIP version 2 (defined in [RFC2453]) supports IPv4. RIPng (defined in [RFC2080]) supports IPv6.

1.1. Terminology

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119].
The following terms are defined in [RFC7950] and are not redefined here:

- augment
- data model
- data node

1.2. Tree Diagrams

A simplified graphical representation of the data model is used in this document. The meaning of the symbols in these diagrams is defined in [I-D.ietf-netmod-yang-tree-diagrams].

1.3. Prefixes in Data Node Names

In this document, names of data nodes, actions, and other data model objects are often used without a prefix, as long as it is clear from the context in which YANG module each name is defined. Otherwise, names are prefixed using the standard prefix associated with the corresponding YANG module, as shown in Table 1.

Table 1: Prefixes and Corresponding YANG Modules

2. Design of the Data Model

2.1. Scope of the Model

The model covers RIP version 2 [RFC2453] and RIPng [RFC2080] protocols. The model is designed to be implemented on a device where RIP version 2 or RIPng is implemented, and can be used to:

- Configure the RIP version 2 or RIPng protocol.
2.1.  Management Capabilities

- Manage the protocol operational behaviors.
- Retrieve the protocol operational status.

The capabilities described in [RFC1724] are covered.

2.2.  Relation with Core Routing Framework

This model augments the core routing data model "ietf-routing" specified in [I-D.ietf-netmod-rfc8022bis].

```
++-rw routing
    +-rw router-id?
    +-rw control-plane-protocols
        |  +-rw control-plane-protocol* [type name]
        |     +-rw type
        |     +-rw name
        |     +-rw rip     <= Augmented by this Model
        ... 
```

The "rip" container instantiates a RIP protocol entity that supports RIP version 2 or RIPng. Depending on the implementation of "ietf-routing", a RIP instance MAY belong to a logical router or network instance.

2.3.  Protocol Configuration

The model structure for the protocol configuration is as shown below:

```
augment /rt:routing/rt:control-plane-protocols/
    rt:control-plane-protocol:
        +-rw rip
            +-rw <per instance configuration>
            +-rw interface* [interface]
                +-rw interface
                    if:interface-ref
                +-rw <per interface configuration>
                +-rw neighbors {explicit-neighbors}?
                    |  +-rw neighbor* [address]
                    |      +-rw address    inet:ip-address
                    |  +-rw <per neighbor configuration> 
```

The model allows to configure the following protocol entities:

- Protocol instance (RIP version 2 or RIPng)
2.4. Protocol States

The model structure for the protocol states is as shown below:

```
augment /rt:routing/rt:control-plane-protocols/
   rt:control-plane-protocol:
     +--rw rip
       +--ro <per instance operational states>
       +--rw interface* [interface]
         |  +--rw interface if:interface-ref
         |  +--ro <per instance operational states>
         |  +--ro statistics (interface-statistics)?
         |     +--ro <per instance statistics>
         +--ro ipv4
           +--ro neighbors
             |  +--ro neighbor* [ipv4-address]
             |     +--ro <per neighbor IPv4 operational states>
             +--ro routes
               +--ro route* [ipv4-prefix]
                 +--ro <IPv4 RIP route states>
           +--ro ipv6
             +--ro neighbors
               |  +--ro neighbor* [ipv6-address]
               |     +--ro <per neighbor IPv6 operational states>
             +--ro routes
               +--ro route* [ipv6-prefix]
                 +--ro ipv6-prefix inet:ipv6-prefix
                 +--ro <IPv4 RIP route states>
           +--ro statistics (global-statistics)?
             +--ro <per instance statistics>
```

This model conforms to the Network Management Datastore Architecture (NMDA) [I-D.ietf-netmod-revised-datastores]. The operational state data is combined with the associated configuration data in the same hierarchy [I-D.ietf-netmod-rfc6087bis]. When protocol states are retrieved from the NMDA operational state datastore, the returned states cover all "config true" (rw) and "config false" (ro) nodes defined in the schema.

The model allows to retrieve protocol states at the following levels:

- Protocol instance (RIP version 2 or RIPng)
2.5. RPC Operations

This model defines one RPC "clear-rip-route" that can be used to clear RIP routes from the routing table.

2.6. Notifications

This model does not define RIP specific notifications. To enable notifications, the mechanism defined in [I-D.ietf-netconf-subscribed-notifications] and [I-D.ietf-netconf-yang-push] can be used. This mechanism currently allows the user to:

- Subscribe notifications on a per client basis.
- Specify subtree filters or xpath filters so that only interested contents will be sent.
- Specify either periodic or on-demand notifications.

2.7. Optional Features

This model defines several features are beyond the basic RIP configuration and it is the responsibility of each vendor to decide whether to support a given feature on a device.

3. Tree Structure

This document defines the YANG module "ietf-rip", which has the following tree structure:

```
module: ietf-rip
    augment /rt:routing/rt:control-plane-protocols
    /rt:control-plane-protocol:
        +--rw rip
            +--rw originate-default-route
                |   +--rw enabled? boolean

RFC Ed.: In this section, replace all occurrences of 'XXXX' with the
actual RFC number (and remove this note).

This document registers the following namespace URIs in the IETF XML
registry [RFC3688]:

--------------------------------------------------------------------
Registrant Contact: The IESG.
XML: N/A, the requested URI is an XML namespace.
--------------------------------------------------------------------

This document registers the following YANG modules in the YANG Module
Names registry [RFC7950]:

--------------------------------------------------------------------
name:         ietf-rip
prefix:       rip
reference:    RFC XXXX
--------------------------------------------------------------------

6. Security Considerations

The YANG module specified in this document defines a schema for data
that is designed to be accessed via network management protocols such
as NETCONF [RFC6241] or RESTCONF [RFC8040]. The lowest NETCONF layer
is the secure transport layer, and the mandatory-to-implement secure
transport is Secure Shell (SSH) [RFC6242]. The lowest RESTCONF layer
is HTTPS, and the mandatory-to-implement secure transport is TLS
[RFC5246].

The NETCONF access control model [RFC6536] provides the means to
restrict access for particular NETCONF or RESTCONF users to a
preconfigured subset of all available NETCONF or RESTCONF protocol
operations and content.

There are a number of data nodes defined in this YANG module that are
writable/creatable/deletable (i.e., config true, which is the
default). These data nodes may be considered sensitive or vulnerable
in some network environments. Write operations (e.g., edit-config) to these data nodes without proper protection can have a negative effect on network operations. These are the subtrees and data nodes and their sensitivity/vulnerability:

\[
\text{/rt:routing/rt:control-plane-protocols/rt:control-plane-protocol/rip:rip}
\]

Unauthorized access to any data node of these subtrees can adversely affect the routing subsystem of both the local device and the network. This may lead to network malfunctions, delivery of packets to inappropriate destinations, and other problems.

Some of the readable data nodes in this YANG module may be considered sensitive or vulnerable in some network environments. It is thus important to control read access (e.g., via get, get-config, or notification) to these data nodes. These are the subtrees and data nodes and their sensitivity/vulnerability:

\[
\text{/rt:routing/rt:control-plane-protocols/rt:control-plane-protocol/rip:rip}
\]

Unauthorized access to any data node of these subtrees can disclose the operational state information of RIP on this device.

Some of the RPC operations in this YANG module may be considered sensitive or vulnerable in some network environments. It is thus important to control access to these operations. These are the operations and their sensitivity/vulnerability:

RPC clear-rip-route:

Unauthorized access to the RPC above can adversely affect the routing subsystem of both the local device and the network. This may lead to network malfunctions, delivery of packets to inappropriate destinations, and other problems.

Appendix A. Data Tree Example

This section contains an example of an instance data tree in the JSON encoding [RFC7951], containing both configuration and state data.

```
+---------------------+
|                     |
| Router 203.0.113.1  |
|                     |
+----------+----------+
|eth1      |192.0.2.1/24|
|192.0.2.2/24    |
+----------+----------+
|Another Router|         |
|             | 198.51.100.0/24|
+---------------------+
```

The configuration instance data tree for Router 203.0.113.1 in the above figure could be as follows:
{
    "ietf-interfaces:interfaces": {
        "interface": [
            {
                "name": "eth1",
                "description": "An interface with RIPv2 enabled.",
                "type": "iana-if-type:ethernetCsmacd",
                "ietf-ip:ipv4": {
                    "address": [
                        {
                            "ip": "192.0.2.1",
                            "prefix-length": 24
                        }
                    ],
                    "forwarding": true
                }
            }
        ],
        "ietf-routing:routing": {
            "router-id": "203.0.113.1",
            "control-plane-protocols": {
                "control-plane-protocol": [
                    {
                        "type": "ietf-rip:ripv2",
                        "name": "ripv2-1",
                        "description": "RIPv2 instance ripv2-1.",
                        "ietf-rip:rip": {
                            "redistribute": {
                                "connected": {
                                }
                            }
                        }
                    }
                ],
                "interfaces": {
                    "interface": [
                        {
                            "interface": "eth1",
                            "split-horizon": "poison-reverse"
                        }
                    ]
                }
            }
        }
    }
}
The corresponding operational state data for Router 203.0.113.1 could be as follows:

```
{
  "ietf-interfaces:interfaces": {
    "interface": [
      {
        "name": "eth1",
        "description": "An interface with RIPv2 enabled.",
        "type": "iana-if-type:ethernetCsmacd",
        "phys-address": "00:0C:42:E5:B1:E9",
        "oper-status": "up",
        "statistics": {
          "discontinuity-time": "2016-10-24T17:11:27+02:00"
        },
        "ietf-ip:ipv4": {
          "forwarding": true,
          "mtu": 1500,
          "address": [
            {
              "ip": "192.0.2.1",
              "prefix-length": 24
            }
          ]
        }
      }
    ],
    "ietf-routing:routing": {
      "router-id": "203.0.113.1",
      "interfaces": {
        "interface": [
          "eth1"
        ]
      },
