TRILL: ESADI (End Station Address Distribution Information) Protocol
<draft-ietf-trill-esadi-09.txt>

Abstract

The IETF TRILL (Transparent Interconnection of Lots of Links) protocol provides least cost pair-wise data forwarding without configuration in multi-hop networks with arbitrary topologies and link technologies. TRILL supports multi-pathing of both unicast and multicast traffic. Devices that implement the TRILL protocol are called TRILL Switches or RBridges (Routing Bridges).

ESADI (End Station Address Distribution Information) is an optional protocol by which a TRILL switch can communicate, in a Data Label (VLAN or Fine Grained Label) scoped way, end station address and reachability information to TRILL switches participating in ESADI for the relevant Data Label. This document updates RFC 6325, specifically the documentation of the ESADI protocol, and is not backwards compatible.

Status of This Memo

This Internet-Draft is submitted to IETF in full conformance with the provisions of BCP 78 and BCP 79.

Distribution of this document is unlimited. Comments should be sent to the TRILL working group mailing list: <trill@ietf.org>.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF), its areas, and its working groups. Note that other groups may also distribute working documents as Internet-Drafts.
Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

The list of current Internet-Drafts can be accessed at http://www.ietf.org/1id-abstracts.html. The list of Internet-Draft Shadow Directories can be accessed at http://www.ietf.org/shadow.html.

1. Introduction

The IETF TRILL (Transparent Interconnection of Lots of Links) protocol [RFC6325] provides least cost pair-wise data forwarding without configuration in multi-hop networks with arbitrary topologies and link technologies, safe forwarding even during periods of temporary loops, and support for multi-pathing of both unicast and multicast traffic. TRILL accomplishes this with the IS-IS (Intermediate System to Intermediate System) [IS-IS] [RFC1195] [RFC7176] link-state routing protocol using a header with a hop count. The design supports optimization of the distribution of multi-destination frames and two types of data labeling: VLANs (Virtual Local Area Networks [RFC6325]) and FGLs (Fine Grained Labels, [RFC7172]). Devices that implement TRILL are called TRILL switches or RBridges (Routing Bridges).

There are five ways a TRILL switch can learn end station addresses, as described in Section 4.8 of [RFC6325]. One of these is the ESADI (End Station Address Distribution Information) protocol, which is an optional Data Label scoped way TRILL switches can communicate, with each other, information such as end station addresses and their TRILL switch of attachment. A TRILL switch that is announcing interest in a Data Label MAY use the ESADI protocol to announce the end station address of some or all of its attached end stations in that Data Label to other TRILL switches that are running ESADI for that Data Label. (In the future, ESADI may also be used for other address and reachability information.)

By default, TRILL switches with connected end stations learn addresses from the data plane when ingressing and egressing native frames although such learning can be disabled. The ESADI protocol’s potential advantages over data plane learning include the following:

1. Security advantages: (1a) The ESADI protocol can be used to announce end stations with an authenticated enrollment (for example enrollment authenticated by cryptographically based EAP (Extensible Authentication Protocol [RFC3748]) methods via [802.1X]). (1b) The ESADI protocol supports cryptographic authentication of its message payloads for more secure transmission.

2. Fast update advantages: The ESADI protocol provides a fast update of end station MAC (Media Access Control) addresses and their TRILL switch of attachment. If an end station is unplugged from one TRILL switch and plugged into another, ingressed frames with that end station’s MAC address as their destination can be black holed. That is, they can be sent just to the older egress TRILL switch that the end station was connected to until cached address information at some remote ingress TRILL switch times out, possibly for tens of seconds [RFC6325].
MAC address reachability information, some ESADI parameters, and optional authentication information are carried in ESADI packets rather than in the TRILL IS-IS protocol. As specified below, ESADI is, for each Data Label, a virtual logical topology overlay in the TRILL topology. An advantage of using ESADI over using TRILL IS-IS is that the end station attachment information is not flooded to all TRILL switches but only to TRILL switches advertising ESADI participation for the Data Label in which those end stations occur.

1.1 Content and Precedence

This document updates [RFC6325], the TRILL base protocol specification, obsoleting and replacing the description of the TRILL ESADI protocol (Section 4.2.5 of [RFC6325] including all subsections), providing more detail on ESADI, updating other ESADI related sections of [RFC6325], and prevailing over [RFC6325] in any case where they conflict. For this reason, familiarity with [RFC6325] is particularly assumed. These changes include a change to the format of ESADI-LSPs that is not backwards compatible; this change is justified by the substantially increased amount of information that can be carried and in light of the very limited, if any, deployment of RFC 6325 ESADI. These changes are further discussed in Appendix A.

Section 2 of this document is the ESADI protocol overview. Section 3 specifies ESADI DRB (Designated RBridge) determination. Section 4 discusses the processing of ESADI PDUs (Protocol Data Units). Section 5 discusses interaction with other modes of end station address learning. And Section 6 describes the ESADI-LSP (Link State PDU) and its contents.

1.2 Terminology

This document uses the acronyms defined in [RFC6325] and the following:

Data Label - VLAN or FGL.

ESADI RBridge - An RBridge that is participating in ESADI for one or more Data Labels.

FGL - Fine Grained Label [RFC7172].

LSP - Link State PDU [IS-IS].
LSP number zero - A Link State PDU with fragment number equal to zero.

PDU - Protocol Data Unit.

TRILL switch - an alternative name for an RBridge.

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119].

Capitalized IANA Considerations terms such as "IETF Review" as to be interpreted as described in [RFC5226].
2. ESADI Protocol Overview

ESADI is a Data Label scoped way for TRILL switches (also known as RBridges) to announce and learn end station addresses rapidly and securely. An RBridge that is announcing participation in ESADI for one or more Data Labels is called an ESADI RBridge.

ESADI is a separate optional protocol from the mandatory TRILL IS-IS implemented by all RBridges in a campus. There is a separate ESADI instance for each Data Label (VLAN or FGL) if ESADI is being used for that Data Label. In essence, for each such Data Label, there is a modified instance of the IS-IS reliable flooding mechanism in which ESADI RBridges may choose to participate. (These are not the instances specified in [RFC6822].) Multiple ESADI instances may share implementation components within an RBridge as long as that sharing preserves the independent operation of each instance of the ESADI protocol. For example, the ESADI link state database could be in a single database with a field in each record indicating the Data Label to which it applies or could be a separate database per Data Label. But the ESADI update process operates separately for each ESADI instance and independently from the TRILL IS-IS update process.

ESADI does no routing calculations so there is no reason for pseudo-nodes in ESADI and none are created (Pseudo-nodes [IS-IS] are a construct for optimizing routing calculations.) Furthermore, there may be a requirement for a relatively large amount of data to be distributed through ESADI which might take a large number of ESADI-LSP fragments. ESADI-LSP, ESADI-CSNP, and ESADI-PSNP (ESADI Link State PDU, Complete Sequence Number PDU, and Partial Sequence Number PDU) payloads are therefore formatted as Extended Level 1 Circuit Scope (E-L1CS) PDUs [FS-LSP] (see also Section 6). This allows up to $2^{16}$ fragments but does not support link state data associated with pseudo-nodes.

After the TRILL header, ESADI packets have an inner Ethernet header with the Inner.MacDA of "All-Egress-RBridges" (formerly called "All-ESADI-RBridges"), an inner Data Label specifying the VLAN or FGL of interest, and the "L2-IS-IS" Ethertype followed by the ESADI payload as shown in Figure 1.
Figure 1. TRILL ESADI Packet Overview

TRILL ESADI packets sent on an Ethernet link are structured as shown below. The outer VLAN tag will not be present if it was not included by the Ethernet port that sent the packet.
Outer Ethernet Header:

```
+---------------------------------+-------+---------------------------------+
| Next Hop Destination Address    |       |
+---------------------------------+-------+---------------------------------+
| Next Hop Destination Addr.      |       |
| Sending RBridge Port MAC Addr.  |       |
+---------------------------------+-------+---------------------------------+
| Sending RBridge Port MAC Address|       |
+---------------------------------+-------+---------------------------------+

...Ethernet frame tagging including optional Outer.VLAN tag...
```

```
| Ethertype = TRILL 0x22F3 |       |
+---------------------------------+-------+---------------------------------+
```

TRILL Header:

```
+---------------------------------+-------+---------------------------------+
| V | R | M|Op-Length| Hop Count |       |
+---------------------------------+-------+---------------------------------+
| Egress Nickname                 |       |
| Ingress (Origin) Nickname       |       |
+---------------------------------+-------+---------------------------------+
```

Inner Ethernet Header:

```
+---------------------------------+-------+---------------------------------+
| All-Egress-RBridges             |       |
+---------------------------------+-------+---------------------------------+
| All-Egress-RBridges cont.       | Origin RBridge MAC Address |       |
+---------------------------------+-------+---------------------------------+
| Origin RBridge MAC Address cont. |       |
+---------------------------------+-------+---------------------------------+
| VLAN or FGL Data Label (4 or 8 bytes) [RFC7172] |       |
+---------------------------------+-------+---------------------------------+
| Ethertype = L2-IS-IS 0x22F4 |       |
+---------------------------------+-------+---------------------------------+
```

ESADI Payload (formatted as IS-IS):

```
+---------------------------------+-------+---------------------------------+
| IS-IS Common Header, IS-IS PDU Specific Fields, IS-IS TLVs |       |
+---------------------------------+-------+---------------------------------+
```

Frame Check Sequence:

```
+---------------------------------+-------+---------------------------------+
| FCS (Frame Check Sequence)      |       |
+---------------------------------+-------+---------------------------------+
```

Figure 2: ESADI Ethernet Link Packet Format

The Next Hop Destination Address or Outer.MacDA is the All-RBridges multicast address if the ESADI PDU is being multicast. If it is being unicast, the Next Hop Destination Address is the unicast address of the next hop RBridge. The VLAN for the Outer.VLAN information, if present, will be the Designated VLAN for the link on which the packet is sent. The V and R fields will be zero while the M field will be one unless the ESADI PDU was unicast, in which case the M field will be zero. The Data Label specified will be the VLAN or FGL to which the ESADI packet applies. The Origin RBridge MAC Address or Inner.MacSA MUST be a MAC address unique across the campus owned by
the RBridge originating the ESADI packet, for example, any of its port MAC addresses if it has any Ethernet ports, and each RBridge MUST use the same Inner.MacSA for all of the ESADI packets that RBridge originates.

TRILL ESADI packets sent on a PPP link are structured as shown below [RFC6361].

PPP Header:
+++
| PPP = TNP (TRILL data) 0x005D |
+++
TRILL Header:
+++++++
| V | R | M|Op-Length| Hop Count |
+++++++
| Egress Nickname |
| Ingress (Origin) Nickname |
+++++++
Inner Ethernet Header:
+++++++
| All-Egress-RBridges |
| All-Egress-RBridges cont. |
| Origin RBridge MAC Address |
| Origin RBridge MAC Address continued |
| VLAN or FCL Data Label (4 or 8 bytes) [RFC7172] ... |
| Ethertype = L2-IS-IS 0x22F4 |
+++++++
ESADI Payload (formatted as IS-IS):
+++++++
| IS-IS Common Header, IS-IS PDU Specific Fields, IS-IS TLVs |
+++++++
PPP Check Sequence:
+++++++
| PPP Check Sequence |

Figure 3: ESADI PPP Link Packet Format

2.1 ESADI Virtual Link

All RBridges forward ESADI packets as if they were ordinary TRILL Data packets. Because of this forwarding, it appears to an instance of the ESADI protocol at an RBridge that it is directly connected by a multi-access virtual link to all RBridges in the campus that are data reachable from it (see Section 2 of [RFC7180]) and are running
ESADI for that Data Label. No "routing" calculation (least cost path or distribution tree construction) ever has to be performed by ESADI. An ESADI RBridge merely transmits the ESADI packets it originates on this virtual link as described for TRILL Data packets in [RFC6325] and [RFC7172]. For multicast ESADI packets it may use any distribution tree that it might use for an ordinary multi-destination TRILL Data packet. RBridges that do not implement the ESADI protocol, do not have it enabled, or are not participating for the Data Label of an ESADI packet do not decapsulate or locally process the TRILL ESADI packet. Thus, ESADI packets are transparently tunneled through transit RBridges.

2.2 ESADI Neighbor Determination

The ESADI instance for Data Label X at an RBridge RB1 determines who its adjacent ESADI neighbors are by examining the TRILL IS-IS link state database for RBridges that are data reachable from RB1 (see Section 2 of [RFC7180]) and are announcing their participation in Data Label X ESADI. When an RBridge RB2 becomes data unreachable from RB1 or the relevant entries for RB2 are purged from the core IS-IS link state database, it is lost as a neighbor and also dropped from any ESADI instances from the point of view of RB1, and when RB2 is no longer announcing participation in Data Label X ESADI, it ceases to be a neighbor for any Data Label X ESADI instance. All these considerations are Data Label scoped. Because of these mechanisms whereby an ESADI instance at an ESADI RBridge can determine its ESADI adjacencies by examining the TRILL IS-IS link state database, there are no "Hellos" sent in ESADI and no adjacency information is carried in ESADI-LSPs.

Participation announcement in a VLAN scoped ESADI instance is through setting a flag bit in the Interested VLANs sub-TLV and announcement for an FGL scoped ESADI instance is through setting a flag bit in the Interested Labels sub-TLV [RFC7176]. (See Section 7.1)

2.3 ESADI Payloads

TRILL ESADI packet payloads are structured like IS-IS Extended Level 1 Circuit Scoped (E-L1CS) LSP, CSNP, and PSNP PDUs [FS-LSP], except as indicated below, but are always TRILL encapsulated on the wire as if they were TRILL Data packets. The information distributed by the ESADI protocol includes a list of local end station MAC addresses connected to the originating RBridge and, for each such address, a one octet unsigned "confidence" rating in the range 0-254 (see
Section 6.2). It is entirely up to the originating RBridge which locally connected MAC addresses it wishes to advertise via ESADI and with what confidence. It MAY advertise all, some, or none of such addresses. In addition, some ESADI parameters of the advertising RBridge (see Section 6.1) and optionally authentication information (see Section 6.3) are included. Future uses of ESADI may distribute other similar address and reachability information.

TRILL ESADI-LSPs MUST NOT contain a Data Label ID in their payload. The Data Label to which the ESADI data applies is the Data Label of the TRILL Data packet enclosing the ESADI payload. If a Data Label ID could occur within the payload, it might conflict with that TRILL Data packet Data Label and could conflict with any future Data Label mapping scheme that may be adopted [VLANmapping]. If a VLAN or FGL ID field within an ESADI-LSP PDU does include a value, that field’s contents MUST be ignored.
3. ESADI DRB (Designated RBridge) Determination

Because ESADI does no adjacency announcement or routing, the ESADI-DRB never creates a pseudonode. But a DRB (Designated RBridge [RFC7177]) is still needed for ESADI-LSP synchronization by issuing ESADI-CSNP PDUs and responding to ESADI-PSNP PDUs.

Generally speaking, the DRB election on the ESADI virtual link (see Section 2.1) operates similarly to the DRB election on a TRILL IS-IS broadcast link, as described in Section 4.2.1 ("DRB Election Details") of [RFC7177], with the following exceptions: In the Data Label X ESADI-DRB election at RB1 on an ESADI virtual link, the candidates are the local ESADI instance for Data Label X and all remote ESADI instances at RBridges that (1) are data reachable from RB1 [RFC7180], and (2) are announcing in their TRILL IS-IS LSP that they are participating in ESADI for Data Label X. The winner is the instance with the highest ESADI Parameter 7-bit priority field with ties broken by System ID, comparing fields as unsigned integers with the larger magnitude considered higher priority. "SNPA/MAC address" is not considered in this tie breaking and there is no "Port ID".
4. ESADI PDU processing

Data Label X ESADI neighbors are usually not connected directly by a physical link, but are always logically connected by a virtual link (see Section 2.1). There could be hundreds or thousands of ESADI RBridges (TRILL switches) on the virtual link. There are only ESADI-LSP, ESADI-CSNP and ESADI-PSNP PDUs used in ESADI. In particular, there are no Hello or MTU PDUs because ESADI does not build a topology, does not do any routing calculations, and does not determine MTU, using the campus Sz. (Sz is the TRILL campus wide minimum link MTU (see [RFC6325] and [RFC7180]).)

4.1 Unicasting ESADI PDUs

For [IS-IS], PDU multicasting is normal on a local link and no effort is made to optimize to unicast because on the typical physical link for which IS-IS was designed (commonly a piece of multi-access Ethernet cable) any frame made the link busy for that frame time. But to ESADI instances, what appears to be a simple multi-access link is generally a set of multi-hop distribution trees that may or may not be pruned. Thus, transmitting a multicast frame on such a tree can impose a substantially greater load than transmitting a unicast frame. This load may be justified if there are likely to be multiple listeners but may not be justified if there is only one recipient of interest. For this reason, under some circumstances, ESADI PDUs MAY be TRILL unicast if it is confirmed that the destination RBridge supports receiving unicast ESADI PDUs (see Section 6.1).

The format of a unicast ESADI packet is the format of a multicast TRILL ESADI packet, in Section 2 above, except as follows:

- On an Ethernet link, in the Outer Ethernet Header the Outer.MacDA is the unicast address of the next hop RBridge.

- In the TRILL header, the M bit is set to zero and the Egress Nickname is the nickname of the destination RBridge.

To support unicasting of ESADI PDUs, Section 4.6.2.2 of [RFC6325] is replaced with the following:

"4.6.2.2. TRILL ESADI Packets

If M=1, the egress nickname designates the distribution tree. The packet is forwarded as described in Section 4.6.2.5. In addition, if the forwarding RBridge is (1) interested in the specified VLAN or Fine Grained Label [RFC7172], (2) implements the TRILL ESADI protocol, and (3) ESADI is enabled for that VLAN or Fine Grained..."
Label, the inner frame is decapsulated and provided to that local ESADI protocol.

If $M=0$ and the egress nickname is not that of the receiving RBridge, the packet is forwarded as for known unicast TRILL Data in Section 4.6.2.4. If $M=0$ and the egress nickname is that of the receiving RBridge and the receiving RBridge supports unicast ESADI PDUs, then the ESADI packet is decapsulated and processed if it meets the three numbered conditions in the paragraph above, otherwise it is discarded.

The references to "4.6.2.2", "4.6.2.4", and "4.6.2.5" above refer to those sections in [RFC6325].

4.2 General Transmission of ESADI PDUs

Following the usual [IS-IS] rules, an ESADI instance does not transmit any ESADI PDUs if it has no ESADI adjacencies. Such transmission would just be a waste of bandwidth.

The MTU available to ESADI payloads is at least 24 bytes less than that available to TRILL IS-IS because of the additional fields required (2(TRILL Ethertype) + 6(TRILL Header) + 6(Inner.MacDA) + 6(Inner.MacSA) + 4/8(Data Label) bytes). Thus the inner ESADI payload, starting with the Intradomain Routing Protocol Discriminator byte, MUST NOT exceed Sz minus 24 for a VLAN ESADI instance or Sz minus 28 for an FGL ESADI instance; however, if a larger payload is received, it is processed normally. (See [RFC6325] and [RFC7180] for discussions of Sz and MTU.)

In all cases where this document says that an ESADI PDU is multicast, if the transmitting RBridge has only one neighbor and that neighbor advertises support for unicast, the PDU MAY be unicast (see Section 4.1).

A priority bit to indicate that an LSP fragment should be flooded with high priority is provided by [FS-LSP]. This bit SHOULD be set on ESADI-LSP fragment zero because it is important that the ESADI Parameters APPsub-TLV get through promptly. This bit SHOULD NOT be set on other ESADI-LSP fragments to avoid giving undue priority to less urgent PDUs.
4.3 General Receipt of ESADI PDUs

In contrast with layer 3 IS-IS PDU acceptance tests, which check the source inner and outer SNPA/MAC in order to verify that a PDU is from an adjacent TRILL switch, in TRILL ESADI, adjacency is based on system ID, so the system ID inside the PDU is all that is tested for.

If an ESADI instance believes that it has no ESADI neighbors, it ignores any ESADI PDUs it receives.

4.4 ESADI Reliable Flooding

The IS-IS reliable flooding mechanism (the Update Process) is modified for ESADI in the ways listed below. Except as otherwise stated, the ESADI update process works as described in [IS-IS], [RFC1195], and [FS-LSP].

When an ESADI instance sees that it has a new ESADI neighbor, its self-originated ESADI-LSP fragments are scheduled to be sent and MAY be unicast to that neighbor if the neighbor is announcing in its LSP that it supports unicast ESADI (see Section 6.1). If all the other ESADI instances for the same Data Label send their self-originated ESADI-LSPs immediately, there may be a surge of traffic to that new neighbor. So the ESADI instances SHOULD wait an interval of time before sending their ESADI-LSP(s) to a new neighbor. The interval time value is up to the device implementation. One suggestion is that the interval time can be assigned a random value with a range based on the RBridge’s nickname (or any one of its nicknames if it holds more than one) such as \((2000 \times \text{nickname} / 2^{16})\) milliseconds assuming "nickname" to be an unsigned quantity.

All the TRILL switches participating in an ESADI instance for some Data Label appear to ESADI to be adjacent. Thus the originator of any active ESADI-LSP fragment always appears to be on link and, to spread the burden of such response, could be the RBridge to respond to any ESADI-CSNP or PSNP request for that fragment. However, under very rare circumstances, it could be that some version of the LSP fragment with a higher sequence number is actually held by another ESADI RBridge on the link, so non-originators need to be able to respond eventually. Thus, when the receipt of a CSNP or PSNP causes the SRMflag (Send Routing Message flag [IS-IS]) to be set for an LSP fragment, action is as specified in [IS-IS] for the originating ESADI RBridge of the fragment; however, at a non-originating ESADI RBridge, when changing the SRMflag from 0 to 1, the lastSent timestamp [IS-IS] is also set to the current time minus \(\text{minimumLSPTimeInterval} \times \text{Random (Jitter)} / 100\).
(where minimumLSPTimeInterval, Random, and Jitter are as in [IS-IS]). This will delay and jitter the transmission of the LSP fragment by non-originators. This gives the originator more time to send the fragment and provides more time for such an originator transmitted copy to traverse the likely multi-hop path to non-originators and clear the SRMflag for the fragment at non-originators.

The multi-hop distribution tree method with Reverse Path Forwarding Check used for multicast distribution by TRILL will typically be less reliable than transmission over a single local broadcast link hop. For LSP synchronization robustness, in addition to sending ESADI-CSNPs as usual when it is DRB, an ESADI RBridge SHOULD also transmit an ESADI-CSNP for an ESADI instance if all of the following conditions are met:

- it sees one or more ESADI neighbors for that instance, and
- it does not believe it is DRB for the ESADI instance, and
- it has not received or sent an ESADI-CSNP PDU for the instance for the average of the CSNP Time (see Section 6.1) of the DRB and its CSNP Time.
5. End Station Addresses

The subsections below discuss end station address considerations in the context of ESADI.

5.1 Learning Confidence Level

The confidence level mechanism [RFC6325] allows an RBridge campus manager to cause certain address learning sources to prevail over others. MAC address information learned through a registration protocol, such as [802.1X] with a cryptographically based EAP [RFC3748] method, might be considered more reliable than information learned through the mere observation of data traffic. When such authenticated learned address information is transmitted via the ESADI protocol, the use of authentication in the TRILL ESADI-LSP packets could make tampering with it in transit very difficult. As a result, it might be reasonable to announce such authenticated information via the ESADI protocol with a high confidence, so it would be used in preference to any alternative learning from data observation.

5.2 Forgetting End Station Addresses

The end station addresses learned through the TRILL ESADI protocol should be forgotten through changes in ESADI-LSPs. The time out of the learned end station address is up to the originating RBridge that decides when to remove such information from its ESADI-LSPs (or up to ESADI protocol timeouts if the originating RBridge becomes unreachable).

If RBridge RBn participating in the TRILL ESADI protocol for Data Label X no longer wishes to participate in ESADI, it ceases to participate by (1) clearing the ESADI participation bit in the appropriate Interested VLANs or Interested Labels sub-TLV and (2) sending a final ESADI-LSP nulling out its ESADI-LSP information.

5.3 Duplicate MAC Address

With ESADI, it is possible to persistently see occurrences of the same MAC address in the same Data Label being advertised as reachable by two or more RBridges. The specification of how to handle this
situation in [RFC6325] is updated by replacing the last sentence of the last paragraph of Section 4.2.6 of [RFC6325] as shown below to provide better traffic spreading while avoiding possible address flip-flopping.

As background, assume some end station or set of end stations ESn have two or more ports with the same MAC address in the same Data Label with the ports connected to different RBridges (RB1, RB2, ...) by separate links. With ESADI, some other RBridge, RB0, can persistently see that MAC address in that Data Label connected to multiple RBridges. When RB0 ingresses a frame, say from ES0, destined for that MAC and label, the current [RFC6325] text permits a wide range of behavior. In particular, [RFC6325] would permit RB0 to use some rule such as always encapsulate to the egress with the lowest System ID, which would put all of this traffic through only one of the egress RBridges and one of the end station ports. With that behavior, there would be no load spreading, even if there were multiple different ingress RBridges and/or different MAC addresses with the same reachability. [RFC6325] also would also permit RB0 to send different traffic to different egresses by doing ECMP at a flow level, which would likely result in return traffic for RB0 to egress to ES0 from various of RB1, RB2, ... for the same MAC and label. The resulting address reachability flip-flopping perceived at RB0 could cause problems.

This update to [RFC6325] avoids these potential difficulties by requiring RB0 to use one of the following two policies: (1) only encapsulate to one egress RBridge for any particular MAC and label but to select that egress pseudo-randomly based on the topology including MAC reachability or (2) if it will not be disturbed by the returning TRILL Data packets showing the same MAC and label flip-flopping between different ingresses, it may use ECMP. Assuming multiple ingress RBridges and/or multiple MAC and label addresses, strategy 1 should result in load spreading without address flip-flopping while strategy 2 will produce better load spreading than strategy 1 but with address flip-flopping from the point of view of RB0.

OLD [RFC6325] Section 4.2.6 text:
  
  "... If confidences are also tied between the duplicates, for consistency it is suggested that RB2 direct all such frames (or all such frames in the same ECMP flow) toward the same egress RBridge; however, the use of other policies will not cause a network problem since transit RBridges do not examine the Inner.MacDA for known unicast frames."

NEW [RFC6325] Section 4.2.6 text:
  
  "...

  If confidences are also tied between the duplicates then RB2 MUST
adopt one of the following two strategies:

1. In a pseudo-random way [RFC4086], select one of the egress RBridges that is least cost from RB2 and to which the destination MAC appears to be attached and send all traffic for the destination MAC and VLAN (or FGL [RFC7172]) to that egress. This pseudo-random choice need only be changed when there is a change in campus topology or MAC attachment information. Such pseudo-random selection will, over a population of ingress RBridges, probabilistically spread traffic over the possible egress RBridges. Reasonable inputs to the pseudo-random selection are the ingress RBridge System ID and/or nickname, the VLAN or FGL, the destination MAC address, and a vector of the RBridges with connectivity to that MAC and VLAN or FGL. There is no need for different RBridges to use the same pseudo-random function.

As an example of such a pseudo-random function, if there are k egress RBridges (RB0, RB1, ..., RB(k-1)) all reporting attachment to address MACx in Data Label DLy, then an ingress RBridge RBin could select the one to which it will send all unicast TRILL Data packets addressed to MACx in DLy based on the following:

\[ \text{FNV-32(RBin} \ | \ \text{MACx} \ | \ \text{DLy} \ | \ \text{RB0} \ | \ \text{RB1} \ | \ldots \ | \ \text{RB(k-1)} \) mod k \]

where FNV is specified in [FNV], RBx means the nickname for RBridge RBx, "\(|\)" means concatenation, MACx is the destination MAC address, DLy is the Data Label, and "mod k" means the integer division remainder of the output of the FNV-32 function considered as a positive integer divided by k.

2. If RB2 supports ECMP and will not be disturbed by return traffic from the same MAC and VLAN (or FGL [RFC7172]) coming from a variety of different RBridges, then it MAY send traffic using ECMP at the flow level to the egress RBridges that are least cost from RB2 and to which the destination MAC appears to be attached."
6. ESADI-LSP Contents

The only PDUs used in ESADI are the ESADI-LSP, ESADI-CSNP, and ESADI-PSNP PDUs. Currently, the contents of an ESADI-LSP consists of zero or more MAC Reachability TLVs, optionally an Authentication TLV, and exactly one ESADI parameter APPsub-TLV. Other similar data may be included in the future and, as in [IS-IS], an ESADI instance ignores any TLVs or sub-TLVs it does not understand. Because these PDUs are formatted as Extended Level 1 Circuit Scope (E-L1CS) PDUs [FS-LSP], the Type and Length fields in the TLVs are 16-bit.

This section specifies the format for the ESADI parameter data APPsub-TLV, gives the reference for the ESADI MAC Reachability TLV, and discusses default authentication configuration.

For robustness, the payload for an ESADI-LSP number zero and any ESADI-CSNP or ESADI-PSNP covering fragment zero MUST NOT exceed 1470 minus 24 bytes in length (1446 bytes) if it has an Inner.VLAN or 1470 minus 28 bytes (1442 bytes) if it has an Inner.FGL. But if an ESADI-LSP number zero or such an ESADI-CSNP or ESADI-PSNP is received that is longer, it is still processed normally. (As stated in Section 4.3.1 of [RFC6325], 1470 bytes was chosen to make it extremely unlikely that a TRILL control packet, even with reasonable additional headers, tags, and/or encapsulation, would encounter MTU problems on an inter-RBridge link.)

6.1 ESADI Parameter Data

The figure below presents the format of the ESADI parameter data. This APPsub-TLV MUST be included in a TRILL GENINFO TLV in ESADI-LSP number zero. If it is missing from ESADI-LSP number zero or if ESADI-LSP number zero is not known, priority for the sending RBridge defaults to 0x40 and CSNP Time defaults to 30. If there is more than one occurrence in ESADI-LSP number zero, the first occurrence will be used. Occurrences of the ESADI parameter data APPsub-TLV in non-zero ESADI-LSP fragments are ignored.
Figure 4. ESADI Parameter APPsub-TLV

Type: set to ESADI-PARAM subTLV (TRILL APPsub-TLV type 0x0001). Two bytes because this APPsub-TLV appears in an Extended TLV [FS-LSP].

Length: Variable with a minimum of 3 but must fit within the ESADI packet. This field is encoded as an unsigned integer in network byte order [FS-LSP].

R: A reserved bit that MUST be sent as zero and ignored on receipt.

Priority: The Priority field gives the originating RBridge’s priority for being DRB on the ESADI instance virtual link (see Section 3) for the Data Label in which the PDU containing the parameter data was sent. It is an unsigned seven-bit integer with larger magnitude indication higher priority. It defaults to 0x40 for an RBridge participating in ESADI for which it has not been configured.

CSNP Time: An unsigned byte that gives the amount of time in seconds during which the originating RBridge, if it is DRB on the ESADI virtual link, will send at least three EASDI-CSNP PDUs. It defaults to 30 seconds for an RBridge participating in ESADI for which it has not been configured.

Flags: A byte of flags associated with the originating ESADI instance as follows:

```
0 1 2 3 4 5 6 7
+-----------------------+
| UN| RESV                |
+-----------------------+
```

The UN flag indicates that the RBridge originating the ESADI-LSP, including this ESADI Parameter Data, will accept and properly process ESADI PDUs sent by TRILL unicast (see Section
4.1). The remaining RESV bits are reserved for future use and MUST be sent as zero and ignored on receipt.

Reserved for future expansion: Future versions of the ESADI Parameters APPsub-TLV may have additional information. A receiving ESADI RBridge ignores any additional data here unless it implements such future expansion(s).

6.2 MAC Reachability TLV

The primary information in TRILL ESADI-LSP PDUs consists of MAC Reachability (MAC-RI) TLVs specified in [RFC6165]. These TLVs contain one or more unicast MAC addresses of end stations that are both on a port and in a VLAN for which the originating RBridge is appointed forwarder, along with the one octet unsigned Confidence in this information with a value in the range 0-254. If such a TLV is received containing a confidence of 255, it is treated as if the confidence was 254. (This is to assure that any received address information can be overridden by local address information statically configured with a Confidence of 255.)

The TLVs in TRILL ESADI PDUs, including the MAC-RI TLV, MUST NOT contain the Data Label ID. If a Data Label ID is present in the MAC-RI TLV, it is ignored. In the ESADI PDU, only the Inner.VLAN or Inner.FGL tag indicates the Data Label to which the ESADI-LSP applies.

6.3 Default Authentication

The Authentication TLV may be included in ESADI PDUs [RFC5310] [IS-IS]. The default for ESADI PDU Authentication is based on the state of TRILL IS-IS shared secret authentication for TRILL IS-IS LSP PDUs. If TRILL IS-IS authentication and ESADI are implemented at a TRILL switch, then ESADI MUST be able to use the authentication algorithms implemented for TRILL IS-IS and implement the keying material derivation function given below. If ESADI authentication has been manually configured, that configuration is not restricted by the configuration of TRILL IS-IS security.

If TRILL IS-IS authentication is not in effect for LSP PDUs originated by a TRILL switch then, by default, ESADI PDUs originated by that TRILL switch are also unsecured.

If such IS-IS LSP PDU authentication is in effect at a TRILL switch
then, unless configured otherwise, ESADI PDUs sent by that switch MUST use the same algorithm in their Authentication TLVs. The ESADI authentication keying material used is derived from the IS-IS LSP shared secret keying material as detailed below. However, such authentication MAY be configured to use some other keying material.

HMAC-SHA256 ( "TRILL ESADI", IS-IS-LSP-shared-key )

In the above HMAC-SHA256 is as described in [FIPS180] [RFC6234] and "TRILL ESADI" is the eleven byte US ASCII [ASCII] string indicated. IS-IS-LSP-shared-key is secret keying material being used by the originating TRILL switch for IS-IS LSP authentication.
7. IANA Considerations

IANA allocation and registry considerations are given below. Three new sub-registries are created in the TRILL Parameters registry located at http://www.iana.org/assignments/trill-parameters, two in Section 7.1 and one in Section 7.2, and various code points assigned.

7.1 ESADI Participation and Capability Flags

IANA Action 1:

IANA is requested to create the following new sub-registry called "Interested VLANs Flag Bits" in the TRILL Parameters registry.

Sub-Registry: Interested VLANs Flag Bits

Registration Procedures: IETF Review

Note: These bits appear in the Interested VLANs record within the Interested VLANs and Spanning Tree Roots Sub-TLV (INT-VLAN) specified in [RFC7176].

References: [RFC7176], [This document]

<table>
<thead>
<tr>
<th>Bit</th>
<th>Mnemonic</th>
<th>Description</th>
<th>Reference</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>M4</td>
<td>IPv4 Multicast Router Attached</td>
<td>[RFC7176]</td>
</tr>
<tr>
<td>1</td>
<td>M6</td>
<td>IPv6 Multicast Router Attached</td>
<td>[RFC7176]</td>
</tr>
<tr>
<td>2</td>
<td></td>
<td>Unassigned</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>ES</td>
<td>ESADI Participation</td>
<td>This document</td>
</tr>
<tr>
<td>4-15</td>
<td></td>
<td>(used for a VLAN ID)</td>
<td>[RFC7176]</td>
</tr>
<tr>
<td>16-19</td>
<td></td>
<td>Unassigned</td>
<td></td>
</tr>
<tr>
<td>20-31</td>
<td></td>
<td>(used for a VLAN ID)</td>
<td>[RFC7176]</td>
</tr>
</tbody>
</table>

The creation of this sub-registry as immediately above assigns bit 3 as the ESADI Participation bit in the Interested VLANs and Spanning Tree Roots Sub-TLV. If the ESADI Participation bit is a one, it indicates that the originating RBridge is participating in ESADI for the indicated Data Label(s).

IANA Action 2:

IANA is requested to create the following new sub-registry called "Interested Labels Flag Bits" in the TRILL Parameters registry.
Sub-Registry: Interested Labels Flag Bits

Registration Procedures: IETF Review

Note: These bits appear in the Interested Labels record within the Interested Labels and Spanning Tree Roots Sub-TLV (INT-LABEL) specified in [RFC7176].

References: [RFC7176], [this document]

<table>
<thead>
<tr>
<th>Bit</th>
<th>Mnemonic</th>
<th>Description</th>
<th>Reference</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>M4</td>
<td>IPv4 Multicast Router Attached</td>
<td>[RFC7176]</td>
</tr>
<tr>
<td>1</td>
<td>M6</td>
<td>IPv6 Multicast Router Attached</td>
<td>[RFC7176]</td>
</tr>
<tr>

<tr>
<td>3</td>
<td>ES</td>
<td>ESADI Participation</td>
<td>This document</td>
</tr>
<tr>
<td>4-7</td>
<td>-</td>
<td>Unassigned</td>
<td></td>
</tr>
</tbody>
</table>

The creation of this sub-registry as immediately above assigns bit 3 as the ESADI Participation bit in the Interested Labels and Spanning Tree Roots Sub-TLV. If the ESADI Participation bit is a one, it indicates that the originating RBridge is participating in ESADI for the indicated Data Label(s).

7.2 TRILL GENINFO TLV

IANA Action 3:

IANA is requested to allocate the IS-IS Application Identifier TBD [1 suggested] under the Generic Information TLV (#251) [RFC6823] for TRILL.

IANA Action 4:

IANA is requested to create a subregistry in the TRILL Parameters Registry as follows:
Sub-Registry: TRILL APPsub-TLV Types under IS-IS TLV #251
Application Identifier #TBD

Registration Procedures: IETF Review with additional
requirements on the documentation of the use being
registered as specified in Section 7.2 of <this
document>.

Note: Types greater than 255 are only usable in contexts
permitting a type larger than one byte, such as Extended
TLVs [FS-LSP].

</tr>
</tbody>
</table>

TRILL APPsub-TLV Types 2 through 254 and 256 through 65534 are
available for assignment by IETF Review. The RFC causing such an
assignment will also include a discussion of security issues and of
the rate of change of the information being advertised. TRILL
APPsub-TLVs MUST NOT alter basic IS-IS protocol operation including
the establishment of adjacencies, the update process, and the
decision process for TRILL IS-IS [IS-IS], [RFC1195], [RFC7177]. The
TRILL Generic Information TLV MUST NOT be used in an IS-IS instance
zero [RFC6822] LSP but may be used in FS-LSPs [FS-LSP].

The V, I, D, and S flags in the initial flags byte of a TRILL Generic
Information TLV have the meanings specified in [RFC6823] but are not
currently used as TRILL operates as a Level 1 IS-IS area and no
semantics are hereby assigned to the inclusion of an IPv4 and/or IPv6
address via the I and V flags. Thus these I and V flags MUST be zero;
however, if either or both is one, the space that should be taken by
and IPv4 and/or IPv6 address respectively is skipped over and
ignored. Furthermore, use of multi-level IS-IS is an obvious
extension for TRILL [MultiLevel] and future IETF Standards Actions
may update or obsolete this specification to provide for the use of
any or all of these flags in the TRILL GENINFO TLV.

The ESADI Parameters information, for which TRILL APPsub-TLV 1 is
hereby assigned, is compact and slow changing (see Section 6.1).

For Security Considerations related to ESADI and the ESADI parameters
APPsub-TLV, see Section 8.
8. Security Considerations

ESADI PDUs can be authenticated through the inclusion of the Authentication TLV [RFC5310]. Defaults for such authentication are described in Section 6.3.

The ESADI-LSP data primarily announces MAC address reachability within a Data Label. Such reachability can, in some cases, be an authenticated registration (for example, a layer 2 authenticated registration using cryptographically based EAP (Extensible Authentication Protocol [RFC3748]) methods via [802.1X]). The combination of these techniques can cause ESADI MAC reachability information to be substantially more trustworthy than MAC reachability learned from observation of the data plane. Nevertheless, ESADI still involves trusting all other RBridges in the TRILL campus, at least those that have the keying material necessary to construct a valid Authentication TLV.

However, there may be cases where it is not necessary to authenticate ESADI PDUs despite using authenticated registration for end stations because of a significant threat of forged packets on end station links when that threat is not present for inter-RBridge trunks. For example a TRILL campus with secure RBridges and inter-RBridge links configured as trunks but some end stations connected via IEEE 802.11 wireless access links might use 802.11 authentication for the connection of such end stations but not necessarily authenticate ESADI PDUs. Note that if the IS-IS LSPs in a TRILL campus are authenticated, perhaps due to a concern about forged packets, the ESADI PDUs will be authenticated by default as provided in Section 6.3.

MAC reachability learned from the data plane (the TRILL default) is overwritten by any future learning of the same type. ESADI advertisements are represented in Data Label scoped link state database. Thus ESADI makes visible any multiple attachments of the same MAC address within a Data Label to different RBridges (see Section 5.3). This may or may not be an error or misconfiguration but ESADI at least makes it explicitly and persistently visible, which would not be the case with data plane learning.

For general TRILL Security Considerations, see [RFC6325].

8.1 Privacy Considerations

The address reachability information distributed by ESADI has substantial privacy considerations under many, but not all, circumstances.
For example, if ESADI were used in a TRILL campus with independent user end stations at the edge, the MAC addresses of such end stations could uniquely identify the users of those end stations. Their reachability would be sensitive information and, particularly if logged, be revealing of their users. On the other hand, if TRILL is being used to implement an Internet Exchange Point (IXP) to connect Internet Service Providers (ISPs), the MAC addresses being advertised in ESADI would typically be those of the ISP’s directly connected IP router ports, since Layer 3 routers bound the TRILL campus, for which there would be few privacy concerns.

However, records of MAC attachment, including a modest amount of history, perhaps a few days worth, can be useful in managing a network and troubleshooting network problems. It might, in some cases, also be legally required or required for billing purposes or the like.

Network operators should seek a reasonable balance between these competing considerations for the circumstances of their particular networks where ESADI is in use. They should not maintain logs of MAC reachability information for any longer than is clearly required.
9. Acknowledgements

The authors thank the following, listed in alphabetic order, for their suggestions and contributions:

   David Black, Somnath Chatterjee, Adrian Farrel, Stephen Farrell, Sujay Gupta, Russ Housley, Pearl Liang, Kathleen Moriarty, Thomas Narten, Erik Nordmark, and Mingui Zhang.

This document was produced with raw nroff. All macros used were defined in the source file.

Appendix A: Interoperability and Changes to [RFC6325]

This appendix summarizes the significant changes this document makes to the TRILL base protocol specification [RFC6325]. Although simultaneous use of [RFC6325] ESADI and ESADI as specified in this document in a TRILL campus is very unlikely due to non-deployment of [RFC6325] ESADI, this Appendix also discusses, for each change, the interoperability considerations should such simultaneous use occur.

A.1 ESADI PDU Changes

The format of ESADI-LSP, ESADI-CSNP, and ESADI-PSNP PDU payloads is changed from the IS-IS Level 1 format [IS-IS] to the Extended Level 1 Circuit Scoped format (E-L1CS) specified in [FS-LSP]. This change is not backwards compatible with [RFC6325]. It is made in light of the 256 times greater information carrying capacity of the E-L1CS format compared with the base IS-IS format. It is anticipated that this greater carrying capacity will be needed, under some circumstances, to carry end station addressing information or other similar address and reachability information that is added to ESADI in the future.

The PDU numbers used for the ESADI LSP, CSNP, and PSNP PDUs in [RFC6325] are 18, 24, and 26 [IS-IS]. With this document, the format changes and the PDU numbers change to 10, 11, and 12 [FS-LSP]. The use of different PDU numbers assures that a PDU will not be mis-parsed. Because of this, implementations of this document and implementations of [RFC6325] ESADI will discard each other’s PDUs. Thus address reachability or other information distributed through either type of ESADI implementation will only be communicated to other implementations of the same type and the two communities will not communicate any information with each other.

Note that RBridges can use the TRILL mandatory-to-implement, enabled-by-default data plane address learning in addition to ESADI. (Section 5 of this document and the material it references explain how to handle conflicts between different sources of address reachability information.) Simply leaving data plane address learning enabled would enable smooth incremental migration from [RFC6325] EASDI to the ESADI specification in this document, should that be necessary. The data plane address learning would fill in any gaps due to non-communication between the two types of ESADI implementation although without the speed or security advantages of ESADI.
A.2 Unicasting Changes

Unicasting of ESADI PDUs is optionally supported including replacing Section 4.6.2.2 of [RFC6325] with the new text given in Section 4.1 of this document. This unicast support is backwards compatible because it is only used when the recipient RBridge signals its support.

A.3 Message Timing Changes and Suggestions

The following timing relevant ESADI message changes and suggestions are included in this document:

1. Provide for staggered delay for non-originators of ESADI-LSP fragments in response to requests for such fragments by CSNP and PSNP messages.

2. Suggest staggered timing of unicast ESADI-LSPs when a new ESADI RBridge appears on the EASDI virtual link.

These relate only to the timing of messages for congestion minimization. Should a message be lost, due to congestion or otherwise, it will be later retransmitted as a normal part of the robust flooding mechanism used by ESADI.

A.4 Duplicate Address Reachability

The handling of persistent reachability of the same MAC within the same Data Label from two or more RBridges is substantially modified including the explicit replacement of some text in Section 4.2.6 of [RFC6325] (see Section 5.3 of this document). There is no problem with a mixture of ESADI implementations in a TRILL campus, some conforming to [RFC6325] and some conforming with this document, for handling this condition. The more implementations conform to the improved behavior specified in this document for this condition, the better the traffic spreading will be and the less likely address flip-flopping problems are.
Appendix Z: Change History

RFC Editor: Please delete this section before publication.

Z.1 From -00 to -01

1. Add Section 6.3 "Default Authentication".
2. Add "Acknowledgements" Section.
3. Change requirement from "MAY" to "SHOULD" for an ESADI RBridge that is not DRB to send an ESADI-CSNP if it does not receive an ESADI-CSNP in long enough.
4. Default CSNP Time was listed as 30 in one place and 40 in another. Change to uniformly specify 30.
5. Update references to RFC 6326 to reference the 6326bis draft.
6. Relax allocation criteria for TRILL APPsub-TLV type code points from Standard Action to IETF Review.
7. Numerous Editorial changes.

Z.2 From -01 to -02

1. Extend to cover FGL and well as VLAN and introduce the term "Data Label" to cover both.
2. Expand number of LSP fragments to $2^{16}$.
3. Simplify neighbor detection to no longer require possession of ESADI-LSP zero.
4. Add update to last sentence of Section 4.2.6 of [RFC6325].
5. Update references for publication of RFCs 6822 and 6823.
6. Additional minor changes.
Z.3 From -02 to -03

1. Replace instances of "IS-IS and data unreachable" with just "data unreachable" as data unreachability implies IS-IS unreachability [RFC7180].

2. With ESADI, there is just one virtual link on which all participating TRILL switches are adjacent. Thus, all of the useful ESADI-LSPs in an ESADI link state database are originated by a station on this virtual link. To avoid overworking the ESADI DRB on the link, ESADI-LSPs sent by a reachable TRILL switch in response to an ESADI-PSNP should be sent by the TRILL switch originating those EASDI-LSPs.

3. Re-organize material on sending and receiving ESADI PDUs into more smaller subsections that cover all the different circumstances.

4. Substantially expand Security Considerations section.

5. Numerous editorial changes.

Z.4 From -03 to -04

2. Update references to RFC 6327 to the rfc6327bis draft.

3. Sort Informational References RFCs in numeric order.

4. Add Appendix A: summary of changes to [RFC6325].

5. Minor editing changes.

Z.5 From -04 to -05

1. Expand Appendix A to be more complete and precise.

2. Add L2-IS-IS Ethertype to Figure 1 so figure and text match.

3. For clarification, add an example pseudo-random function to the new text in Section 5.3.

4. Eliminate possible unicasting of PSNPs.
5. Provide for staggered delay for non-originators of ESADI-LSP fragments in response to requests for such fragments by CSNP and PSNP messages.

6. In Section 7.2, cover inclusion in FS-LSPs as permitted by [FS-LSP].

7. Some editing changes including expanding "MAC&label".

**Z.6 From -05 to -06**

1. In Section 4.3: "a an adjacent" -> "an adjacent".

2. In Section 4.4: "( 100 - Random (Jitter) )" -> Random(Jitter)".

3. Add one Acknowledgement.

**Z.7 From -06 to -07**

Update based on GENART and IANA reviews:

1. Update and extend the first paragraph of Section 1.1 and items 2 and 3 in Appendix A with particular attention to how this document updates RFC 6325 and backwards compatibility.

2. Minor edits to the first part of Section 2 to clarify "pseudo-nodes" and the use of common components inside an RBridge implementation of the independent ESADI instances.

3. Add references to [RFC7172] inside Figures 2 and 3.

4. Section 2.1, minor edits for clarity.

5. Section 2.2, "is ignored" -> "MUST be ignored".

6. Section 3, minor edit to clarify DRB election references.

7. Explain source of "1470 bytes" in Section 6.

8. Add new second paragraph to Section 8 to clarify cases where you might want authenticated end-station registration but would not need ESADI-PDU authentication.

9. Substantial editorial changes to the IANA Considerations (Section
7), based on IANA review, to clarify the requested IANA actions.

10. Update Acknowledgements.

11. Other minor editorial changes.

Z.8 From -07 to -08

Update primarily based on IESG review

1. Re-write of Appendix A to add substantial interoperability considerations material.

2. Addition of Privacy Considerations subsection to Security Considerations.

3. Addition of references to [RFC5310] in connection with authentication of ESADI PDUs.

4. Update draft references due to RFC publications and add some Acknowledgements.

5. Minor editorial changes.

Z.9 From -08 to -09

1. Fix a few typos.

2. Clarify encoding of Length field in Section 6.1.

3. Clarify some wording in Section 1, list item 2.
