Abstract

This document proposes a Context-Aware Navigator Protocol (CAN) for IP-based vehicular networks for cooperative navigation among vehicles in road networks. This CAN aims at the enhancement of driving safety through a light-weight driving information sharing method. The CAN protocol uses an IPv6 Neighbor Discovery (ND) option to convey driving information such as a vehicle’s position, speed, acceleration/deceleration, and direction, and a driver’s driving action (e.g., braking and accelerating).

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at https://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on May 7, 2020.

1.  Introduction

The enhancement of driving safety is one of objectives in cooperative driving in vehicular networks. Dedicated Short-Range Communications (DSRC) is for vehicular communications [DSRC]. IEEE has standardized a family standard suite of Wireless Access in Vehicular Environments (WAVE) [WAVE]. Also, IETF has standardized an IPv6 packet delivery protocol over IEEE 802.11-OCB (Outside the Context of a Basic Service Set) [ID-IPv6-802.11-OCB], which is a MAC protocol for vehicles in WAVE.

A vehicle equipped with various sensors and the a DSRC device can sense its surrounding environment including its neighboring vehicles, and share the sensed data and its mobility information (e.g., position, speed, acceleration/deceleration, and direction) with its neighboring vehicles. This information sharing allows vehicles to assess the collision risk and make their maneuver change to avoid an accident in a prompt way. That is, the capability of sensing, computing, and communication of vehicles enables them to understand the driving environment and situation (i.e., context), and cooperate with each other during their navigation.

The driving information sharing enables Context-Aware Navigator (CAN) where each vehicle can display its neighboring vehicles, pedestrians, and obstacles in its navigation system [CASD]. With this CAN, a driver can make a better decision on driving to avoid an accident, and an autonomous vehicle can control its maneuver to escape from a possible fatality in advance.
For this CAN service, this document proposes a light-weight data sharing protocol using a new IPv6 Neighbor Discovery (ND) option for Vehicle Mobility Information, which is called Vehicle Mobility Information (VMI) option. This VMI option can be included by a Neighbor Advertisement (NA) message in Vehicular Neighbor Discovery (VND) [ID-Vehicular-ND].

There are two messages for the CAN service with the VMI option such as Cooperation Context Message (CCM) and Emergency Context Message (ECM). The CCM is a message to deliver a vehicle’s motion information (e.g., position, speed, acceleration/deceleration, direction) and a driver’s driving action (e.g., braking and accelerating) to its neighboring vehicles for cooperative driving. The ECM is a message to notify a vehicle’s neighboring vehicles of an emergency situation (e.g., an accident and dangerous situation). The ECM has a higher priority than the CCM such that the ECM needs to be disseminated faster than the CCM in vehicular networks.

2. Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC 2119 [RFC2119].

3. Terminology

This document uses the terminology described in [ID-IPWAVE-PS].

4. Vehicle Mobility Information Option

Vehicle Mobility Information (VMI) option is an IPv6 ND option to convey either a CCM or ECM. Figure 1 shows the format of the VMI option.

Figure 1: Vehicle Mobility Information (VMI) Option Format
Fields:

Type  8-bit identifier of the VMI option type as assigned by the IANA: TBD

Length  8-bit unsigned integer. The length of the option (including the Type and Length fields) is in units of 8 octets. The value is 3.

Message  8-bit identifier of the VMI message type as CCM (0) and ECM (1).

Reserved1  This field is unused. It MUST be initialized to zero by the sender and MUST be ignored by the receiver.

Reserved2  This field is unused. It MUST be initialized to zero by the sender and MUST be ignored by the receiver.

Mobility Information  128-bit mobility information. It contains a vehicle’s motion information (e.g., position, speed, acceleration/deceleration, direction) and a driver’s driving action (e.g., braking and accelerating) for CCM. Also, it contains a vehicle’s emergency information (e.g., obstacle information and accident information).

A CCM in a VMI option can be included in an NA message that a vehicle transmits periodically to announce its existence and routing information to its one-hop neighboring vehicles [ID-Vehicular-ND].

An ECM in a VMI option can be included in an NA message that a vehicle transmits to immediately announce an emergency situation to its one-hop neighboring vehicles [ID-Vehicular-ND].

To let the vehicles take an immediate action on an emergency situation, the ECM has a higher priority than the CCM. Thus, if a vehicle has an ECM and a CCM to send, it SHOULD transmit the ECM earlier than the CCM.

5. Security Considerations

This document shares all the security issues of the IPv6 ND protocol. This document can get benefits from Secure Neighbor Discovery (SEND) [RFC3971] in order to protect exchanged messages from possible security attacks.
