Abstract

This document defines a YANG data model that provides a data structure that can be used to configure an implementation of the Transport Services Interface to establish connections suitable for sending and receiving data over the internet or local networks. This document is intended to supplement or merge with draft-ietf-taps-interface.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at https://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on January 8, 2020.

1. Introduction

This document is an attempt to concretize the properties and objects of the TAPS interface described in [I-D.ietf-taps-interface], under the architecture described in [I-D.ietf-taps-arch].

A TAPS-compliant implementation SHOULD provide a language-appropriate way to configure a PreConnection using YANG instance data for this model, and SHOULD provide an API that outputs the YANG instance data for an established Connection.

An implementation MAY also provide appropriate APIs for directly editing the objects without using YANG. It’s RECOMMENDED where possible to use names that mechanically translate to the names in the YANG data model, using capitalization and punctuation conventions as expected for the language of the implementation.

Non-TAPS extensions to API objects that directly edit TAPS properties are RECOMMENDED to include "ext", "EXT", or "Ext" as a prefix to any extension properties or methods, to avoid colliding with future TAPS extensions.

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [RFC2119] [RFC8174] when, and only when, they appear in all capitals, as shown here.
1.1. A Note On The Use Of YANG

Although YANG was originally designed to model data for NETCONF, YANG can be used in other ways as well, as described by Section 4.1 of [RFC7950].

This usage is not primarily targeted at NETCONF, but rather at Application Programming Interfaces for libraries that set up connections for sending and receiving data over the internet. However, use of YANG in this context provides a semantically clear, well defined, extensible, cross-platform method for configuring connection objects suitable for replacing BSD sockets in a wide variety of applications.

2. Tree Diagram

Tree diagrams used in this document follow the notation defined in [RFC8340].

module: ietf-taps-api
  +++rw preconnection
    +++rw local-endpoints* [id]
      +++rw id               string

      +++rw per-msg-checksum-len-recv? preference-level
3. Examples

3.1. Basic Client Connection

The API is designed to allow defaults to fill out almost everything. This example shows the minimal preconnection configuration input data to open a reliable transfer to example.com, via any supported reliable transport protocol on the default port or ports.

```
{
    "ietf-taps-api:preconnection":{
      "remote-endpoints":{
        "id":"option1",
        "remote-host":"example.com"
      }
    }
}
```

Basic Client Connection
Due to the defaults recommended in (TBD: fix reference) Section 5 of draft-ietf-taps-interface-02, implementations SHOULD treat this basic example equivalently to the same example with the defaults explicitly provided:

```
{
  "ietf-taps-api:preconnection":{
    "remote-endpoints":{
      "id":"option1",
      "remote-host":"example.com"
    },
    "transport-properties":{
      "reliability":"require",
      "preserve-order":"require",
      "congestion-control":"require"
    }
  }
}
```

Basic Client Connection Explicitly Declaring Defaults

3.2. Customized Connections

In some cases, applications may have explicit preferences, either dynamically inferred from past statistics or configured via system or app preferences of some kind.

These examples demonstrates adding constraints on the endpoints when opening a connection.

3.2.1. Require Wi-Fi

This example demonstrates an app that requires the use of a wireless interface:
{  "ietf-taps-api:preconnection":{   "remote-endpoints":{    {      "id":"option1",      "remote-host":"example.com"    },   },   "transport-properties":{    "interface":{      {        "preference":"avoid",        "value":"iana-if-type:capwapDot11Profile"      }    }   }  }
}

Figure 1: Customized to require wireless.

3.3. Send and Receive Multicast

Sending to a multicast group is the same as any non-reliable, non-ordered connection:
Figure 2: PreConnection for Sending Multicast

Receiving multicast is similar. It may use remote-endpoint to specify a source-specific multicast subscription, or exclude it to specify any-source multicast.
3.4. Connecting Through a Stun Server

STUN server connections are a local-endpoint property, and can be configured the same way.
Figure 4: Connect through a STUN server

4. YANG Module

<CODE ENDS>

Figure 5: TAPS Interface YANG model

5. Security Considerations

This document describes a configuration system for an API that may replace sockets. All security considerations applicable to socket programming should be carefully considered by implementors.

(TBD: surely there is a sane reference, but also fill this out with something less laughable. In particular, enumerate which options should be privileged operations or not to preserve the security of
BSD sockets, such as it is. And maybe another layer of restriction recommendations for sandboxed or browser systems.)

6. IANA Considerations

IANA is requested to add the YANG model in Section 4 to the yang-parameters registry.

7. Normative References

[I-D.ietf-taps-arch]

[I-D.ietf-taps-interface]

Appendix A. Future Work

TBD if adopted:

- Review [RFC8407] guidelines for YANG authors and reviewers, make sure they are followed.

- Start a reference implementation. No doubt it will highlight many model problems.

- many more config examples with use cases

- Look into providing explicit layers that support some kind of pass-thru, instead of having all properties in big groups of properties.
