YANG data model for BGP Segment Routing Extensions
draft-majumdar-spring-bgp-sr-yang-00

Abstract

This document defines a YANG data model that can be used to configure and manage Segment Routing extensions in BGP.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at https://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on January 8, 2020.

1. Introduction

YANG [RFC6020] is a data definition language that was introduced to define the contents of a conceptual data store that allows networked devices to be managed using NETCONF [RFC6241]. YANG is proving relevant beyond its initial confines, as bindings to other interfaces (e.g. ReST) [RFC8040] and encodings other than XML (e.g. JSON) [RFC7951] are being defined. Furthermore, YANG data models can be used as the basis of implementation for other interfaces, such as CLI and programmatic APIs.

This document defines the YANG model for Segment Routing specific extensions in BGP.
1.1. Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [RFC2119] [RFC8174] when, and only when, they appear in all capitals, as shown here.

2. BGP Segment Routing Yang model

2.1. Overview

Segment Routing (SR), as defined in [RFC8402], leverages the source routing paradigm where a node steers a packet through an ordered list of instructions, called segments. SR, thus, allows enforcing a flow through any topological path and/or service chain while maintaining per-flow state only at the ingress nodes to the SR domain.

When applied to ipv6 data-plane (i.e. SRv6), the ordered set of instructions are realized via SRv6 SIDs. The various functions and behaviors corresponding to network programming using SRv6 are specified in [I-D.ietf-spring-srv6-network-programming].

This document defines Yang model for the Segment Routing extensions applicable for BGP as following:

- Prefix sid extensions in the context of SR MPLS, as described in [I-D.ietf-idr-bgp-prefix-sid].
- Egress Peer Engineering (EPE) as described in [I-D.ietf-spring-segment-routing-central-epe].

The Yang extensions proposed in this model augment the base BGP model defined in [I-D.ietf-idr-bgp-model].

Note: Base BGP model does not have a common structure for BGP RIB. The placeholder containers defined in this model can be removed once base BGP model has the BGP RIB structure.

The modeling in this document complies with the Network Management Datastore Architecture (NMDA) [RFC8342]. The operational state data is combined with the associated configuration data in the same hierarchy [RFC8407]. When protocol states are retrieved from the NMDA operational state datastore, the returned states cover all "config true" (rw) and "config false" (ro) nodes defined in the schema.
2.2. SR Prefix SID (SR MPLS)

Prefix SID attribute in BGP in the context of SR MPLS, carries the label index and SRGB block information.

- The configuration to attach the label index is modeled as a new route-policy set action. BGP policy actions from the BGP policy module defined in base BGP Yang model [I-D.ietf-idr-bgp-model] are augmented for this purpose.
- The configuration related to SR Mapping Server in the context of BGP prefix SID, is TBD.
- Prefix SID attribute received with the BGP route is modeled under BGP AF mode for select address families. This information is applicable per route.

2.3. Egress Peer Engineering

Egress Peer Engineering (EPE) in the context of Segment Routing is described in [I-D.ietf-spring-segment-routing-central-epe]. EPE is enabled in the context of BGP neighbor session. Three different types of EPE SIDs namely, Peer node SID, Peer adjacency SID and Peer set SID correspond to the segments required for source routed inter domain paths. EPE SID(s) for each type above, can be statically configured or dynamically allocated by the node. Further, FRR backup policy and backup SID can be specified per EPE. The configuration and state for the EPE parameters is modeled by augmenting the neighbor container defined in the base BGP model [I-D.ietf-idr-bgp-model]. The configuration and the applied config state are applicable for neighbor-groups as well.

6. IANA Considerations

7. Security Considerations

The transport protocol used for sending the BGP Segment Routing data MUST support authentication and SHOULD support encryption. The data-model by itself does not create any security implications.

This draft does not change any underlying security issues inherent in [I-D.ietf-idr-bgp-model].
8. Acknowledgements
