Abstract

Some applications require the ability to provide an elevated probability of session establishment to specific sessions in times of network congestion. When supported over the Internet Protocol suite, this may be facilitated through a network layer admission control solution that supports prioritized access to resources (e.g., bandwidth). These resources may be explicitly set aside for prioritized sessions, or may be shared with other sessions. This document specifies extensions to the Resource ReSerVation Protocol (RSVP) that can be used to support such an admission priority capability at the network layer.

Based on current security concerns, these extensions are targeting applicability within a single domain.

Appendix A. Examples of Bandwidth Allocation Model For

Introduction

Some applications require the ability to provide an elevated probability of session establishment to specific sessions in times of network congestion.

Solutions to meet this requirement for elevated session establishment probability may involve session layer capabilities prioritizing access to resources controlled by the session control function. As
an example, entities involved in session control (such as SIP user agents, when the Session Initiation Protocol (SIP) [RFC3261], is the session control protocol in use) can influence their treatment of session establishment requests (such as SIP requests). This may include the ability to “queue” session establishment requests when those can not be immediately honored (in some cases with the notion of “bumping”, or “displacement”, of less important session establishment requests from that queue). It may include additional mechanisms such as exemption from certain network management controls, and alternate routing.

Solutions to meet the requirement for elevated session establishment probability may also take advantage of network layer admission control mechanisms supporting admission priority. Networks usually have engineered capacity limits that characterize the maximum load that can be handled (say, on any given link) for a class of traffic while satisfying the quality of service requirements of that traffic class. Admission priority may involve setting aside some network resources (e.g. bandwidth) not of the engineered capacity limits for the prioritized sessions only. Or alternatively, it may involve allowing the prioritized sessions to seize additional resources beyond the engineered capacity limits applied to normal sessions. This document specifies the necessary extensions to support such admission priority when network layer admission control is performed using the Resource ReSerVation Protocol (RSVP) ([RFC2205]).

[RFC3181] specifies the Signaled Preemption Priority Policy Element that can be signaled in RSVP so that network node may take into account this policy element in order to preempt some previously admitted low priority sessions in order to make room for a newer, higher priority session. In contrast, this document specifies new RSVP extensions to increase the probability of session establishment without preemption of existing sessions. This is achieved by
engineered capacity techniques in the form of bandwidth allocation models. In particular this document specifies two new RSVP Policy Elements allowing the admission priority to be conveyed inside RSVP signaling messages so that RSVP nodes can enforce selective bandwidth admission control decision based on the session admission priority. Appendix A of this document also provides examples of bandwidth allocation models which can be used by RSVP-routers to enforce such admission priority on every link. A given reservation may be signaled with the admission priority extensions specified in the present document, with the preemption priority specified in [RFC3181] or with both.

Based on current security concerns, these extensions are targeting applicability within a single domain.

1.1. Terminology

This document assumes the terminology defined in [RFC2753]. For convenience, the definition of a few key terms is repeated here:

- **Policy Decision Point (PDP):** The point where policy decisions are made.
- **Local Policy Decision Point (LPDP):** PDP local to the network element.
- **Policy Enforcement Point (PEP):** The point where the policy decisions are actually enforced.
- **Policy Ignorant Node (PIN):** A network element that does not explicitly support policy control using the mechanisms defined in [RFC2753].

2. Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC 2119 [RFC2119].

3. Overview of RSVP extensions and Operations

Let us consider the case where a session requires elevated probability of establishment, and more specifically that the preference to be granted to this session is in terms of network layer "admission priority" (as opposed to preference granted through preemption of existing sessions). By "admission priority" we mean allowing the priority session to seize network layer resources from the engineered capacity that has been set-aside for priority sessions (and not made available to normal sessions), or alternatively...
allowing the priority session to seize additional resources beyond the engineered capacity limits applied to normal sessions.

Session establishment can be conditioned to resource-based and policy-based network layer admission control achieved via RSVP signaling. In the case where the session control protocol is SIP, the use of RSVP-based admission control in conjunction with SIP is specified in [RFC3312].

Devices involved in the session establishment are expected to be aware of the application-level priority requirements of prioritized sessions. For example, considering the case where the session control protocol is SIP, the SIP user agents may be made aware of the resource priority requirements of a given session using the "Resource-Priority" header mechanism specified in [RFC4412]. The end-devices involved in the upper-layer session establishment simply need to copy the application-level resource priority requirements (e.g. as communicated in SIP "Resource-Priority" header) inside the new RSVP Application-Level Resource Priority Policy Element defined in this document.

Conveying the application-level resource priority requirements inside the RSVP message allows this application level requirement to be mapped/remapped into a different RSVP "admission priority" at a policy boundary based on the policy applicable in that policy area. In a typical model (see [RFC2753]) where PDPs control PEPs at the periphery of the policy area (e.g. on the first hop router), PDPs would interpret the RSVP Application-Level Resource Priority Policy Element and map the requirement of the prioritized session into an RSVP "admission priority" level. Then, PDPs would convey this information inside the new Admission Priority Policy Element defined in this document. This way, the RSVP admission priority can be communicated to downstream PEPs (i.e. RSVP Routers) of the same policy domain, which have LPDPs but no controlling PDP. In turn, this means the necessary RSVP Admission priority can be enforced at every RSVP hop, including all the (possibly many) hops which do not have any understanding of Application-Level Resource Priority semantics. It is not expected that the RSVP Application-Level Resource Priority Header Policy Element would be taken into account at RSVP-hops within a given policy area. It is expected to be used at policy area boundaries only in order to set/reset the RSVP Admission Priority Policy Element.

Remapping by PDPs of the Admission Priority Policy Element from the Application-Level Resource Priority Policy Element may also be used at boundaries with other signaling protocols, such as the NSIS Signaling Layer Protocol (NSLP) for QoS Signaling ([I-D.ietf-nsis-qos-nslp]).

As can be observed, the framework described above for mapping/remapping application level resource priority requirements into an
RSVP admission priority can also be used together with [RFC3181] for mapping/remapping application level resource priority requirements into an RSVP preemption priority (when preemption is indeed deemed necessary by the prioritized session handling policy). In that case, when processing the RSVP Application-Level Resource Priority Policy Element, the PDPs at policy boundaries (or between various QoS signaling protocols) can map it into an RSVP "preemption priority" info. This Preemption priority info comprises a setup preemption level and a defending preemption priority level that can then be encoded inside the Preemption Priority Policy Element of [RFC3181].

Appendix B provides examples of various hypothetical policies for prioritized session handling, some of them involving admission priority, some of them involving both admission priority and preemption priority. Appendix B also identifies how the Application-Level Resource Priority needs to be mapped into RSVP policy elements by the PDPs to realize these policies.

3.1. Operations of Admission Priority

The RSVP Admission Priority policy element defined in this document allows admission bandwidth to be allocated preferentially to prioritized sessions. Multiple models of bandwidth allocation MAY be used to that end.

A number of bandwidth allocation models have been defined in the IETF for allocation of bandwidth across different classes of traffic trunks in the context of Diffserv-aware MPLS Traffic Engineering. Those include the Maximum Allocation Model (MAM) defined in [RFC4125], the Russian Dolls Model (RDM) specified in [RFC4127] and the Maximum Allocation model with Reservation (MAR) defined in [RFC4126]. These same models MAY however be applied for allocation of bandwidth across different levels of admission priority as defined in this document. Appendix A provides an illustration of how these bandwidth allocation models can be applied for such purposes and also introduces an additional bandwidth allocation model that we term the Priority Bypass Model (PrBM). It is important to note that the models described and illustrated in Appendix A are only informative and do not represent a recommended course of action.

We can see in these examples how the RSVP Admission Priority can be used by RSVP routers to influence their admission control decision (for example by determining which bandwidth pool is to be used by RSVP for performing its bandwidth allocation) and therefore to increase the probability of reservation establishment. In turn, this increases the probability of application level session establishment for the corresponding session.

4. New Policy Elements
The Framework document for policy-based admission control [RFC2753] describes the various components that participate in policy decision making (i.e., PDP, PEP and LPDP).

As described in Section 3 of the present document, the Application-Level Resource Priority Policy Element and the Admission Priority Policy Element serve different roles in this framework:

- the Application-Level Resource Priority Policy Element conveys application level information and is processed by PDPs
- the emphasis of Admission Priority Policy Element is to be simple, stateless, and light-weight such that it can be processed internally within a node’s LPDP. It can then be enforced internally within a node’s PEP. It is set by PDPs based on processing of the Application-Level Resource Priority Policy Element.

[RFC2750] defines extensions for supporting generic policy based admission control in RSVP. These extensions include the standard format of POLICY_DATA objects and a description of RSVP handling of policy events.

The POLICY_DATA object contains one or more of Policy Elements, each representing a different (and perhaps orthogonal) policy. As an example, [RFC3181] specifies the Preemption Priority Policy Element. This document defines two new Policy Elements called:

- the Admission Priority Policy Element
- the Application-Level Resource Priority Policy Element

### 4.1. Admission Priority Policy Element

The format of the Admission Priority policy element is as shown in Figure 1:

```
     0 0 0 1 1 2 2 3
0 . . 7 8 . . 5 6 . . 3 4 . . 1
+-------------+-------------+-------------+-------------+
|  Length     | P-Type = ADMISSION_PRI |
+-------------+-------------+-------------+-------------+
|  Flags      | M. Strategy | Error Code | Reserved   |
+-------------+-------------+-------------+-------------+
|   Reserved  | Adm. Priority|
+-------------+-------------+-------------+-------------+

Figure 1: Admission Priority Policy Element
```

where:
o Length: 16 bits
  * Always 12. The overall length of the policy element, in bytes.

o P-Type: 16 bits
  * ADMISSION_PRI = To be allocated by IANA (see "IANA Considerations" section)

o Flags: Reserved
  * SHALL be set to zero on transmit and SHALL be ignored on reception

o Merge Strategy: 8 bits (applicable to multicast flows)
  * values are defined by corresponding registry maintained by IANA (see "IANA Considerations" section)

o Error code: 8 bits (applicable to multicast flows)
  * values are defined by corresponding registry maintained by IANA (see "IANA Considerations" section)

o Reserved: 8 bits
  * SHALL be set to zero on transmit and SHALL be ignored on reception

o Reserved: 24 bits
  * SHALL be set to zero on transmit and SHALL be ignored on reception

o Adm. Priority (Admission Priority): 8 bits (unsigned)
  * The admission control priority of the flow, in terms of access to network bandwidth in order to provide higher probability of session completion to selected flows. Higher values represent higher priority. A given Admission Priority is encoded in this information element using the same value as when encoded in the "Admission Priority" field of the "Admission Priority" parameter defined in [I-D.ietf-nsis-qspec]. In other words, a given value inside the Admission Priority information element defined in the present document or inside the [I-D.ietf-nsis-qspec] Admission Priority field refers to the same admission priority. Bandwidth allocation models such as those described in Appendix A are to be used by the RSVP router to achieve such increased probability of session establishment. The admission priority value effectively indicates which bandwidth constraint(s) of the bandwidth constraint model in
use is(are) applicable to admission of this RSVP reservation.

Note that the Admission Priority Policy Element does NOT indicate that this RSVP reservation is to preempt any other RSVP reservation. If a priority session justifies both admission priority and preemption priority, the corresponding RSVP reservation needs to carry both an Admission Priority Policy Element and a Preemption Priority Policy Element. The Admission Priority and Preemption Priority are handled by LPDPs and PEPs as separate mechanisms. They can be used one without the other, or they can be used both in combination.

4.1.1. Admission Priority Merging Rules

This section discusses alternatives for dealing with RSVP admission priority in case of merging of reservations. As merging applies to multicast, this section also applies to multicast sessions.

The rules for merging Admission Priority Policy Elements are defined by the value encoded inside the Merge Strategy field in accordance with the corresponding IANA registry. The merge strategies (and associated values) defined by the present document are the same as those defined in [RFC3181] for merging Preemption Priority Policy Elements (see "IANA Considerations" section).

The only difference with [RFC3181] is that this document does not recommend any merge strategies for Admission Priority, while [RFC3181] recommends the first of these merge strategies for Preemption Priority. Note that with the Admission Priority (as is the case with the Preemption Priority), "Take highest priority" translates into "take the highest numerical value".

4.2. Application-Level Resource Priority Policy Element

The format of the Application-Level Resource Priority policy element is as shown in Figure 2:

```
| Length                    | P-Type = APP_RESOURCE_PRI |
+---------------------------+---------------------------+  // ALRP List
//                             +---------------------------+  // ALRP List
```

Figure 2: Application-Level Resource Priority Policy Element

where:

- Length:
The length of the policy element (including the Length and P-Type) is in number of octets (MUST be a multiple of 4) and indicates the end of the ALRP list.

- P-Type: 16 bits
  - APP_RESOURCE_PRI = To be allocated by IANA (see "IANA Considerations" section)

- ALRP List:
  - List of ALRP where each ALRP is encoded as shown in Figure 3.

\[
\begin{array}{cccccccc}
0 & . & 0 & \ldots & 1 & 1 & 2 & 2 & 3 \\
0 & \ldots & 7 & 8 & \ldots & 5 & 6 & \ldots & 3 & 4 & \ldots & 1 \\
\end{array}
\]

\hspace{1cm} +---------------------------+-------------+-------------+
\hspace{1cm} | ALRP Namespace            | Reserved    | ALRP Value   |
\hspace{1cm} +---------------------------+-------------+-------------+

Figure 3: Application-Level Resource Priority

where:

- ALRP Namespace (Application-Level Resource Priority Namespace): 16 bits (unsigned)
  - Contains a numerical value identifying the namespace of the application-level resource priority. This value is encoded as per the "Resource Priority Namespaces" IANA registry. (See IANA Considerations section for the request to IANA to extend the registry to include this numerical value).

- Reserved: 8 bits
  - SHALL be set to zero on transmit and SHALL be ignored on reception.

- ALRP Value: (Application-Level Resource Priority Value): 8 bits (unsigned)
  - Contains the priority value within the namespace of the application-level resource priority. This value is encoded as per the "Resource Priority Priority-Value" IANA registry. (See IANA Considerations section for the request to IANA to extend the registry to include this numerical value).

4.2.1. Application-Level Resource Priority Modifying and Merging Rules

When POLICY_DATA objects are protected by integrity, LPDPs should not attempt to modify them. They MUST be forwarded as-is to ensure their...
security envelope is not invalidated.

In case of multicast, when POLICY_DATA objects are not protected by integrity, LPDPs MAY merge incoming Application-Level Resource Priority elements to reduce their size and number. When they do merge those, LPDPs MUST do so according to the following rule:

- The ALRP List in the outgoing APP_RESOURCE_PRI element MUST contain all the ALRPs appearing in the ALRP List of an incoming APP_RESOURCE_PRI element. A given ALRP MUST NOT appear more than once. In other words, the outgoing ALRP List is the union of the incoming ALRP Lists that are merged.

As merging applies to Multicast, this rule also applies to Multicast sessions.

4.3. Default Handling

As specified in section 4.2 of [RFC2750], Policy Ignorant Nodes (PINs) implement a default handling of POLICY_DATA objects ensuring that those objects can traverse PIN nodes in transit from one PEP to another. This applies to the situations where POLICY_DATA objects contain the Admission Priority Policy Element and the ALRP Policy Element specified in this document, so that those can traverse PIN nodes.

Section 4.2 of [RFC2750] also defines a similar default behavior for policy-capable nodes that do not recognized a particular Policy Element. This applies to the Admission Priority Policy Element and the ALRP Policy Element specified in this document, so that those can traverse policy-capable nodes that do not support thes extensions defined in the present document.

5. Security Considerations

As this document defines extensions to RSVP, the security considerations of RSVP apply. Those are discussed in [RFC2205], [RFC4230] and [I-D.ietf-tsvwg-rsvp-security-groupkeying]. Approaches for addressing those concerns are discussed further below.

A subset of RSVP messages are signaled with the Router Alert Option (RAO) ([RFC2113], [RFC2711]). The security aspects and common practices around the use of the current IP Router Alert option and consequences on the use of IP Router Alert by applications such as RSVP are discussed in [I-D.rahman-rtg-router-alert-considerations]. As mentioned earlier, based on current security concerns (some of them associated with RAO), the extensions defined in this document are targeting applicability within a single domain.

The ADMISSION_PRI and APP_RESOURCE_PRI Policy Elements defined in this document are signaled by RSVP through encapsulation in a Policy
Data object as defined in [RFC2750]. Therefore, like any other Policy Elements, their integrity can be protected as discussed in section 6 of [RFC2750] by two optional security mechanisms. The first mechanism relies on RSVP Authentication as specified in [RFC2747] and [RFC3097] to provide a chain of trust when all RSVP nodes are policy capable. With this mechanism, the INTEGRITY object is carried inside RSVP messages. The second mechanism relies on the INTEGRITY object within the POLICY_DATA object to guarantee integrity between RSVP Policy Enforcement Points (PEPs) that are not RSVP neighbors.

5.1. Use of RSVP Authentication between RSVP neighbors

RSVP authentication can be used between RSVP neighbors that are policy capable. RSVP Authentication (defined in [RFC2747] and [RFC3097]) SHOULD be supported by an implementation of the present document.

With RSVP authentication, the RSVP neighbors use shared keys to compute the cryptographic signature of the RSVP message. [I-D.ietf-tsvwg-rsvp-security-groupkeying] discusses key types, key provisioning methods as well as their respective applicability.

5.2. Use of INTEGRITY object within the POLICY_DATA object

The INTEGRITY object within the POLICY_DATA object can be used to guarantee integrity between non-neighboring RSVP PEPs. This is useful only when some RSVP nodes are Policy Ignorant Nodes (PINs). The INTEGRITY object within the POLICY_DATA object MAY be supported by an implementation of the present document.

Details for computation of the content of the INTEGRITY object can be found in Appendix B of [RFC2750]. This states that the Policy Decision Point (PDP), at its discretion, and based on destination PEP/PDP or other criteria, selects an Authentication Key and the hash algorithm to be used. Keys to be used between PDPs can be distributed manually or via standard key management protocol for secure key distribution.

Note that where non-RSVP hops may exist in between RSVP hops, as well as where RSVP capable Policy Ignorant Nodes (PINs) may exist in between PEPs, it may be difficult for the PDP to determine what is the destination PDP for a POLICY_DATA object contained in some RSVP messages (such as a Path message). This is because in those cases the next PEP is not known at the time of forwarding the message. In this situation, key shared across multiple PDPs may be used. This is conceptually similar to the use of key shared across multiple RSVP neighbors discussed in [I-D.ietf-tsvwg-rsvp-security-groupkeying]. We observe also that this issue may not exist in some deployment scenarios where a single (or low number of) PDP is used to control all the PEPs of a region (such as an administrative domain). In such
scenarios, it may be easy for a PDP to determine what is the next hop
PDP, even when the next hop PEP is not known, simply by determining
what is the next region that will be traversed (say based on the
destination address).

6. IANA Considerations

As specified in [RFC2750], Standard RSVP Policy Elements (P-type
values) are to be assigned by IANA as per "IETF Consensus" policy
following the policies outlined in [RFC2434] (this policy is now
called "IETF Review" as per [RFC5226]).

IANA needs to allocate two P-Types from the Standard RSVP Policy
Element range:

- one P-Type to the Admission Priority Policy Element
- one P-Type to the Application-Level Resource Priority Policy
  Element.

In section 3.1, the present document defines a Merge Strategy field
inside the Admission Priority policy element. IANA needs to create a
registry for this field and allocate the following values:

- 1: Take priority of highest QoS
- 2: Take highest priority
- 3: Force Error on heterogeneous merge

Following the policies outlined in [RFC5226], numbers in the range
4-127 are allocated according to the "IETF Review" policy, numbers in
the range 128-240 as "First Come First Served" and numbers between
241-255 are reserved for "Private Use". Value 0 is Reserved (for

In section 3.1, the present document defines an Error Code field
inside the Admission Priority policy element. IANA needs to create a
registry for this field and allocate the following values:

- 0: NO_ERROR Value used for regular ADMISSION_PRI elements
- 2: HETEROGENEOUS This element encountered heterogeneous merge

Following the policies outlined in [RFC5226], numbers in the range
3-127 are allocated according to the "IETF Review" policy, numbers in
the range 128-240 as "First Come First Served" and numbers between
241-255 are reserved for "Private Use". Value 1 is Reserved (for

The present document defines an ALRP Namespace field in section 3.2.
that contains a numerical value identifying the namespace of the application-level resource priority. The IANA already maintains the Resource-Priority Namespaces registry (under the SIP Parameters) listing all such namespace. However, that registry does not currently allocate a numerical value to each namespace. Hence, this document requests the IANA to extend the Resource-Priority Namespaces registry in the following ways:

- a new column should be added to the registry
- the title of the new column should be "Namespace Numerical Value *
- in the Legend, add a line saying "Namespace Numerical Value = the unique numerical value identifying the namespace"
- add a line at the bottom of the registry stating the following "* : [RFCXXX] " where XXX is the RFC number of the present document
- allocate an actual numerical value to each namespace in the registry and state that value in the new "Namespace numerical Value *" column.

A numerical value should be allocated immediately by IANA to all existing namespace. Then, in the future, IANA should automatically allocate a numerical value to any new namespace added to the registry.

The present document defines an ALRP Priority field in section 3.2 that contains a numerical value identifying the actual application-level resource priority within the application-level resource priority namespace. The IANA already maintains the Resource-Priority Priority-values registry (under the SIP Parameters) listing all such priorities. However, that registry does not currently allocate a numerical value to each priority-value. Hence, this document requests the IANA to extend the Resource-Priority Priority-Values registry in the following ways:

- for each namespace, the registry should be structured with two columns
- the title of the first column should read "Priority Values (least to greatest)"
- the first column should list all the values currently defined in the registry (e.g. for the drsn namespace: "routine", "priority", "immediate", "flash", "flash-override", "flash-override-override" for the drsn namespace)
- the title of the second column should read "Priority Numerical Value *"
At the bottom of the registry, add a "Legend" with a line saying "Priority Numerical Value = the unique numerical value identifying the priority within a namespace".

Add a line at the bottom of the registry stating the following "* : [RFCXXX] " where XXX is the RFC number of the present document.

Allocate an actual numerical value to each and state that value in the new "Priority Numerical Value *" column.

A numerical value should be allocated immediately by IANA to all existing priority. Then, in the future, IANA should automatically allocate a numerical value to any new namespace added to the registry. The numerical value must be unique within each namespace. For the initial allocation, within each namespace, values should be allocated in decreasing order ending with 0 (so that the greatest priority is always allocated value 0). For example, in the drsn namespace, "routine" would be allocated numerical value 5 and "flash-override-override" would be allocated numerical value 0.

Appendix A. Examples of Bandwidth Allocation Model for Admission Priority

Sections A.1 and A.2 respectively illustrate how the Maximum Allocation Model (MAM) ([RFC4125]) and the Russian Dolls Model (RDM) ([RFC4127]) can be used for support of admission priority. The Maximum Allocation model with Reservation (MAR) ([RFC4126]) could also be used in a similar manner for support of admission priority. Section A.3 illustrates how a simple "Priority Bypass Model" can also be used for support of admission priority.

For simplicity, operations with only a single "priority" level (beyond non-priority) are illustrated here; However, the reader will appreciate that operations with multiple priority levels can easily be supported with these models.

In all the figures below:

- x represents a non-priority session
- o represents a priority session

A.1. Admission Priority with Maximum Allocation Model (MAM)

This section illustrates operations of admission priority when a Maximum Allocation Model (MAM) is used for bandwidth allocation across non-priority traffic and priority traffic. A property of the Maximum Allocation Model is that priority traffic can not use more than the bandwidth made available to priority traffic (even if the non-priority traffic is not using all of the bandwidth available for it).

Figure 4: MAM Bandwidth Allocation

Figure 4 shows a link within a routed network conforming to this document. On this link are two amounts of bandwidth available to two types of traffic: non-priority and priority.

If the non-priority traffic load reaches the maximum bandwidth available for non-priority, no additional non-priority sessions can be accepted even if the bandwidth reserved for priority traffic is not currently fully utilized.

With the Maximum Allocation Model, in the case where the priority load reaches the maximum bandwidth reserved for priority sessions, no additional priority sessions can be accepted.

As illustrated in Figure 4, an operator may map the MAM model onto the Engineered Capacity limits according to different policies. At one extreme, where the proportion of priority traffic is reliably known to be fairly small at all times and where there may be some safety margin factored in the engineered capacity limits, the operator may decide to configure the bandwidth available for non-priority use to the full engineered capacity limits; effectively allowing the priority traffic to ride within the safety margin of this engineered capacity. This policy can be seen as an economically attractive approach as all of the engineered capacity is made available to non-priority sessions. This policy is illustrated as (1) in Figure 4. As an example, if the engineered capacity limit on a given link is X, the operator may configure the bandwidth available to non-priority traffic to X, and the bandwidth available to priority traffic to 5% of X. At the other extreme, where the proportion of priority traffic may be significant at times and the engineered capacity limits are very tight, the operator may decide to configure the bandwidth available to non-priority traffic and the bandwidth available to priority traffic such that their sum is equal to the
engineered capacity limits. This guarantees that the total load across non-priority and priority traffic is always below the engineered capacity and, in turn, guarantees there will never be any QoS degradation. However, this policy is less attractive economically as it prevents non-priority sessions from using the full engineered capacity, even when there is no or little priority load, which is the majority of time. This policy is illustrated as (3) in Figure 4. As an example, if the engineered capacity limit on a given link is X, the operator may configure the bandwidth available to non-priority traffic to 95% of X, and the bandwidth available to priority traffic to 5% of X. Of course, an operator may also strike a balance anywhere in between these two approaches. This policy is illustrated as (2) in Figure 4.

Figure 5 shows some of the non-priority capacity of this link being used.

---

### Figure 5: Partial load of non-priority calls

Figure 6 shows the same amount of non-priority load being used at this link, and a small amount of priority bandwidth being used.
Figure 6: Partial load of non-priority calls & partial load of priority calls

Figure 7 shows the case where non-priority load equates or exceeds the maximum bandwidth available to non-priority traffic. Note that additional non-priority sessions would be rejected even if the bandwidth reserved for priority sessions is not fully utilized.

Figure 7: Full non-priority load & partial load of priority calls

Figure 8 shows the case where the priority traffic equates or exceeds the bandwidth reserved for such priority traffic. In that case additional priority sessions could not be accepted. Note that this does not mean that such sessions are dropped altogether: they may be handled by mechanisms, which are beyond the scope of this particular document (such as establishment through preemption of existing non-priority sessions, or such as queuing of new priority session requests until capacity becomes available again for priority traffic).
A.2. Admission Priority with Russian Dolls Model (RDM)

This section illustrates operations of admission priority when a Russian Dolls Model (RDM) is used for bandwidth allocation across non-priority traffic and priority traffic. A property of the Russian Dolls Model is that priority traffic can use the bandwidth which is not currently used by non-priority traffic.

As with the MAM model, an operator may map the RDM model onto the Engineered Capacity limits according to different policies. The operator may decide to configure the bandwidth available for non-priority use to the full engineered capacity limits; As an example, if the engineered capacity limit on a given link is X, the operator may configure the bandwidth available to non-priority traffic to X, and the bandwidth available to non-priority and priority traffic to 105% of X.

Alternatively, the operator may decide to configure the bandwidth available to non-priority and priority traffic to the engineered capacity limits; As an example, if the engineered capacity limit on a given link is X, the operator may configure the bandwidth available to non-priority traffic to 95% of X, and the bandwidth available to non-priority and priority traffic to X.

Finally, the operator may decide to strike a balance in between. The considerations presented for these policies in the previous section in the MAM context are equally applicable to RDM.

Figure 9 shows the case where only some of the bandwidth available to non-priority traffic is being used and a small amount of priority traffic is in place. In that situation both new non-priority sessions and new priority sessions would be accepted.
Figure 9: Partial non-priority load & Partial Aggregate load

Figure 10 shows the case where all of the bandwidth available to non-priority traffic is being used and a small amount of priority traffic is in place. In that situation new priority sessions would be accepted but new non-priority sessions would be rejected.

Figure 10 shows the case where only some of the bandwidth available to non-priority traffic is being used and a heavy load of priority traffic is in place. In that situation both new non-priority sessions and new priority sessions would be accepted. Note that, as illustrated in Figure 10, priority sessions use some of the bandwidth currently not used by non-priority traffic.
Figure 11: Partial non-priority load & Heavy Aggregate load

Figure 12 shows the case where all of the bandwidth available to non-priority traffic is being used and all of the remaining available bandwidth is used by priority traffic. In that situation new non-priority sessions would be rejected. In that situation new priority sessions could not be accepted right away. Those priority sessions may be handled by mechanisms, which are beyond the scope of this particular document (such as established through preemption of existing non-priority sessions, or such as queuing of new priority session requests until capacity becomes available again for priority traffic).

Figure 12: Full non-priority load & Full Aggregate load

A.3. Admission Priority with Priority Bypass Model (PrBM)

This section illustrates operations of admission priority when a simple Priority Bypass Model (PrBM) is used for bandwidth allocation across non-priority traffic and priority traffic. With the Priority Bypass Model, non-priority traffic is subject to resource based
admission control while priority traffic simply bypasses the resource
based admission control. In other words:

- when a non-priority session arrives, this session is subject to
  bandwidth admission control and is accepted if the current total
  load (aggregate over non-priority and priority traffic) is below
  the engineered/allocated bandwidth.

- when a priority session arrives, this session is admitted
  regardless of the current load.

A property of this model is that a priority session is never
rejected.

The rationale for this simple scheme is that, in practice in some
networks:

- the volume of priority sessions is very low for the vast majority
  of time, so it may not be economical to completely set aside
  bandwidth for priority sessions and preclude the utilization of
  this bandwidth by normal sessions in normal situations

- even in congestion periods where priority sessions may be more
  heavily used, those always still represent a fairly small
  proportion of the overall load which can be absorbed within the
  safety margin of the engineered capacity limits. Thus, even if
  they are admitted beyond the engineered bandwidth threshold, they
  are unlikely to result in noticeable QoS degradation.

As with the MAM and RDM model, an operator may map the Priority
Bypass model onto the Engineered Capacity limits according to
different policies. The operator may decide to configure the
bandwidth limit for admission of non-priority traffic to the full
engineered capacity limits; As an example, if the engineered capacity
limit on a given link is X, the operator may configure the bandwidth
limit for non-priority traffic to X. Alternatively, the operator may
decide to configure the bandwidth limit for non-priority traffic to
below the engineered capacity limits (so that the sum of the non-
priority and priority traffic stays below the engineered capacity);
As an example, if the engineered capacity limit on a given link is X,
the operator may configure the bandwidth limit for non-priority
traffic to 95% of X. Finally, the operator may decide to strike a
balance in between. The considerations presented for these policies
in the previous sections in the MAM and RDM contexts are equally
applicable to the Priority Bypass Model.

Figure 13 illustrates the bandwidth allocation with the Priority
Bypass Model.
Figure 13: Priority Bypass Model Bandwidth Allocation

Figure 14 shows some of the non-priority capacity of this link being used. In this situation, both new non-priority and new priority sessions would be accepted.

Figure 14: Partial load of non-priority calls

Figure 15 shows the same amount of non-priority load being used at this link, and a small amount of priority bandwidth being used. In this situation, both new non-priority and new priority sessions would be accepted.
Figure 15: Partial load of non-priority calls & partial load of priority calls

Figure 16 shows the case where aggregate non-priority and priority load exceeds the bandwidth limit for admission of non-priority traffic. In this situation, any new non-priority session is rejected while any new priority session is admitted.

A.4. Admission Priority with Temporary Allocation Model (TAM)

This section illustrates operations of admission priority when a Temporary Allocation Model (TAM) is used for bandwidth allocation across non-priority traffic and priority traffic. According to the characters of emergency services, burstiness and short duration, there are two periods. One is the emergency period and the other is non-emergency period. The emergency service can be regarded as priority traffic, while the normal service is non-priority service. In the non-emergency period, there is only non-priority traffic. So the bandwidth is available to all the traffic.
Figure 17 shows all the bandwidth is available for non-priority traffic in the non-emergency period and some amount of non-priority load being used at this link.

![TAM Bandwidth Allocation for non-Emergency](image)

When one or more emergency service requests arrive at PEP or the time for emergency period arrives (for example, the operator set the time <9:00~11:00> for emergency period), the operator configure the maximum bandwidth available for non-priority, no additional non-priority sessions can be accepted even if the bandwidth reserved for priority traffic is not currently fully utilized. If the current non-priority traffic exceeds the maximum bandwidth which is available to non-priority traffic, then the operator chooses some of the sessions to be teared down in order to make sure there is a portion of bandwidth available for priority use.

The same as the other bandwidth allocation models, an operator may map the TAM model onto the Engineered Capacity limits according to different policies. As an example, if the engineered capacity limit on a given link is X, the operator may configure the bandwidth available to non-priority traffic to 95% of X in the emergency period. When a priority session (emergency service) arrives, this session is admitted regardless of the current load. Finally, the operator may decide to strike a balance in between. The considerations presented for these policies in the MAM, RDM and PrBM contexts are equally applicable to the Priority Bypass Model.

Figure 18 illustrates the bandwidth allocation with the Temporary Allocation Model in the emergency periods.
Figure 18: Temporary Allocation Model Bandwidth Allocation for Emergency

Figure 19 shows some of the non-priority capacity and priority capacity of this link being used. In this situation, both new non-priority and new priority sessions would be accepted.

Figure 19: Partial load of non-priority calls & partial load of priority calls

Figure 20 shows the case where aggregate non-priority and priority load exceeds the bandwidth limit for admission of non-priority traffic. In the situation, any new non-priority session is rejected while any new priority session is admitted.
Figure 20: Full non-priority load

Figure 21 shows the case when one or more emergency service requests arrive at PEP or the time for emergency period arrives, non-priority load exceeds the bandwidth limit for admission of non-priority traffic.

Figure 21: Non-priority traffic load at the beginning of Emergency

Figure 22 shows the operator chooses some of non-priority sessions to be teared down and any new non-priority session is rejected while any new priority session is admitted.
Appendix B. Example Usages of RSVP Extensions

This section provides examples of how RSVP extensions defined in this document can be used (in conjunctions with other RSVP functionality and SIP functionality) to enforce different hypothetical policies for handling prioritized sessions in a given administrative domain. This Appendix does not provide additional specification. It is only included in this document for illustration purposes.

We assume an environment where SIP is used for session control and RSVP is used for resource reservation.

We refer here to "Session Queueing" as the set of "session" layer capabilities that may be implemented by SIP user agents to influence their treatment of SIP requests. This may include the ability to "queue" session requests when those can not be immediately honored (in some cases with the notion of "bumping", or "displacement", of less important session requests from that queue). It may include additional mechanisms such as exemption from certain network management controls, and alternate routing.

We only mention below the RSVP policy elements that are to be enforced by PEPs. It is assumed that these policy elements are set at a policy area boundary by PDPs. The Admission Priority and Preemption Priority RSVP policy elements are set by PDPs as a result of processing the Application Level Resource Priority Policy Element (which is carried in RSVP messages).

If one wants to implement a prioritized service purely based on Session Queueing, one can achieve this by signaling prioritized sessions:

- using "Resource-Priority" header in SIP
If one wants to implement a prioritized service based on Session Queueing and on "prioritized access to network layer resources", one can achieve this by signaling prioritized sessions:

- using "Resource-Priority" header in SIP
- using Admission-Priority Policy Element in RSVP
- not using Preemption Policy Element in RSVP

Establishment of prioritized sessions will not result in preemption of any session. Different bandwidth allocation models can be used to offer different "prioritized access to network resources". Just as examples, this includes strict setting aside of capacity for prioritized sessions as well as simple bypass of admission limits for prioritized sessions.

If one wants to implement a prioritized service based on Session Queueing, on "prioritized access to network layer resources", and ensures that (say) "Prioritized-1" sessions can preempt "Prioritized-2" sessions, but non-prioritized sessions are not affected by preemption, one can do that by signaling prioritized sessions:

- using "Resource-Priority" header in SIP
- using Admission-Priority Policy Element in RSVP
- using Preemption Policy Element in RSVP with:
  * setup (Prioritized-1) > defending (Prioritized-2)
  * setup (Prioritized-2) <= defending (Prioritized-1)
  * setup (Prioritized-1) <= defending (Non-Prioritized)
  * setup (Prioritized-2) <= defending (Non-Prioritized)

If one wants to implement a prioritized service based on Session Queueing, on "prioritized access to network layer resources", and ensure that prioritized sessions can preempt regular sessions, one could do that by signaling Prioritized sessions:

- using "Resource-Priority" header in SIP
- using Admission-Priority Policy Element in RSVP
If one wants to implement a prioritized service based on Session Queueing, on "prioritized access to network layer resources", and ensure that prioritized sessions can partially preempt regular sessions (i.e. reduce their reservation size), one could do that by signaling prioritized sessions:

- using "Resource-Priority" header in SIP
- using Admission-Priority Policy Element in RSVP
- using Preemption in Policy Element RSVP with:
  * setup (Prioritized) > defending (Non-Prioritized)
  * setup (Non-Prioritized) <= defending (Prioritized)
- activate RFC4495 RSVP Bandwidth Reduction mechanisms
