Extensions to IKEv1 and IKEv2 to indicate use of Better-Than-Nothing-Security

draft-richardson-btns-ikeextensions-00.txt

Status of this Memo

By submitting this Internet-Draft, each author represents that any applicable patent or other IPR claims of which he or she is aware have been or will be disclosed, and any of which he or she becomes aware will be disclosed, in accordance with Section 6 of BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF), its areas, and its working groups. Note that other groups may also distribute working documents as Internet-Drafts.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

The list of current Internet-Drafts can be accessed at http://www.ietf.org/ietf/1id-abstracts.txt.

The list of Internet-Draft Shadow Directories can be accessed at http://www.ietf.org/shadow.html.

This Internet-Draft will expire on August 5, 2007.

Abstract

This document specifies how to use the Internet Key Exchange (IKE) protocols, such as IKEv1 and IKEv2, to setup "unauthenticated" security associations (SAs) for use with the IPsec Encapsulating Security Payload (ESP) and the IPsec Authentication Header (AH). This is part of the Better-Than-Nothing-Security (BTNS) work. Two optional IKE extensions are documented here, and the format for one certificate payload type is fully specified.

   Intellectual Property and Copyright Statements ......... 10
1. Introduction

When two nodes decide to use BTNS, they may wish to communicate this intention to the remote party.

There are no protocol reasons to require this intention to be communicated, however, it is useful for diagnostic purposes to be able to indicate this fact in the IKE negotiation.

As part of the BTNS IKE negotiation, it will be necessary for the parties to exchange authentication keying material, and one option is to use the certificate payload. The use of Raw RSA Key type (11) is clarified with some examples.
2. IKE Notify

A new notify message is defined for both IKEv1 [RFC2408] and IKEv2 [RFC4306]. The name of the new notify is BTNS_AUTHENTICATED, and the notify number is TBD1.

This notify message MAY appear in any exchange of phase 1 (IKEv1), and in any exchange of the PARENT_SA (IKEv2). It SHOULD be sent in after the phase 1 SA has become private, since there is little reason to advise a third party of what kind of authentication is being done.

This means it SHOULD be sent during the third exchange of MAIN MODE (IKEv1), in the second exchange of Aggressive Mode (IKEv1), and during the second exchange of IKEv2.

Note: Aggressive mode is SHOULD NOT be used for BTNS.
3. Exchange of public keys

A BTNS negotiation MUST include a public key for each end-point. This key will be carried in a Certificate Payload (section 3.6 of [RFC4306] and section 3.9 of [RFC2408]). There are several options as to how to carry the key.

The public KEY MUST be sent in a Certificate Type 11: Raw RSA Key. This code point is hereby defined for IKEv1 identically to IKEv2.

An implementation MAY also include the same public KEY in a Certificate Payload of type 1 (PKCS #7 wrapped X.509), and it may be self-signed or relative to some CA.

An IKEv2 implementation MAY also include the same public KEY as a Hash and URL of X.509 certificate bundle (type 13), or certificate (type 12). (In general, an implementation should not send both type 1 and types 12 or 13, as it would be redundant.)

An implementation MAY also send additional Certificate Payload types which it believes may be useful, provided that they all lead to the same RSA key. An implementation SHOULD avoid using so many Certificate Payload types that it causes the IKE messages to be fragmented.

An implementation receiving more than one Certificate Payload SHOULD use the following sources to arrive at a public key to use to authenticate the peer, in the following order:

- a preconfigure RSA key contained in a local trusted store.
- an in-band X.509 certificate that can be verified against a locally trusted root CA
- a certificate or certificate bundle retrieved from the indicated URL, that matches the hash, and can be verified
- the key contained in the raw RSA Key payload

All Certificate Payload types other than type 11 are optional, and type 11 is mandatory, so there will always be a public key available to confirm the signature on in the IKE AUTH payload.

The additional payloads are present to deal with the situations where the trust relationship may in fact be asymmetrical, such as for the Asymmetrical SAB (A-SAB), and for the Asymmetrical IKE CBB (AI-CBB). (see [I-D.ietf-btns-prob-and-applic])
4. IANA Considerations

Please assign NOTIFY Type TBD1. from the Notify-Types in the ipsec-registry of IKEv1.

Please assign NOTIFY Type TBD1. from the IKEv2 Notify Message Types table of the ikev2-parameters registry.
5. Security Considerations

This document does not introduce any new mechanisms or modes to IKEv1 or IKEv2. It details the order in which to look for authentication data for a protocol which does not in itself require any authentication data.
