Abstract

An Oblivious Pseudorandom Function (OPRF) is a two-party protocol for computing the output of a PRF. One party (the server) holds the PRF secret key, and the other (the client) holds the PRF input. The ‘obliviousness’ property ensures that the server does not learn anything about the client’s input during the evaluation. The client should also not learn anything about the server’s secret PRF key. Optionally, OPRFs can also satisfy a notion ‘verifiability’ (VOPRF). In this setting, the client can verify that the server’s output is indeed the result of evaluating the underlying PRF with just a public key. This document specifies OPRF and VOPRF constructions instantiated within prime-order groups, including elliptic curves.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at https://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on September 12, 2019.

1. Introduction

A pseudorandom function (PRF) F(k, x) is an efficiently computable function with secret key k on input x. Roughly, F is pseudorandom if the output y = F(k, x) is indistinguishable from uniformly sampling any element in F’s range for random choice of k. An oblivious PRF (OPRF) is a two-party protocol between a prover P and verifier V where P holds a PRF key k and V holds some input x. The protocol allows both parties to cooperate in computing F(k, x) with P’s secret key k and V’s input x such that: V learns F(k, x) without learning anything about k; and P does not learn anything about x. A Verifiable OPRF (VOPRF) is an OPRF wherein P can prove to V that F(k, x) was computed using key k, which is bound to a trusted public key Y = kG. Informally, this is done by presenting a non-interactive zero-knowledge (NIZK) proof of equality between (G, Y) and (Z, M), where Z = kM for some point M.

OPRFs have been shown to be useful for constructing: password-protected secret sharing schemes [JKK14]; privacy-preserving password stores [SJKS17]; and password-authenticated key exchange or PAKE [OPAQUE]. VOPRFs are useful for producing tokens that are verifiable by V. This may be needed, for example, if V wants assurance that P did not use a unique key in its computation, i.e., if V wants key consistency from P. This property is necessary in some applications, e.g., the Privacy Pass protocol [PrivacyPass], wherein this VOPRF is used to generate one-time authentication tokens to bypass CAPTCHA challenges. VOPRFs have also been used for password-protected secret sharing schemes e.g. [JKXX16].

This document introduces an OPRF protocol built in prime-order groups, applying to finite fields of prime-order and also elliptic curve (EC) settings. The protocol has the option of being extended
to a VOPRF with the addition of a NIZK proof for proving discrete log equality relations. This proof demonstrates correctness of the computation using a known public key that serves as a commitment to the server's secret key. In the EC setting, we will refer to the protocol as ECOPRF (or ECVOPRF if verifiability is concerned). The document describes the protocol, its security properties, and provides preliminary test vectors for experimentation. The rest of the document is structured as follows:

- **Section 2**: Describe background, related work, and use cases of OPRF/VOPRF protocols.
- **Section 3**: Discuss security properties of OPRFs/VOPRFs.
- **Section 4**: Specify an authentication protocol from OPRF functionality, based in prime-order groups (with an optional verifiable mode). Algorithms are stated formally for OPRFs in Section 4.3 and for VOPRFs in Section 4.4.
- **Section 5**: Specify the NIZK discrete logarithm equality (DLEQ) construction used for constructing the VOPRF protocol.
- **Section 6**: Specifies how the DLEQ proof mechanism can be batched for multiple VOPRF invocations, and how this changes the protocol execution.
- **Section 7**: Considers explicit instantiations of the protocol in the elliptic curve setting.
- **Section 8**: Discusses the security considerations for the OPRF and VOPRF protocol.
- **Section 9**: Discusses some existing applications of OPRF and VOPRF protocols.
- **Appendix A**: Specifies test vectors for implementations in the elliptic curve setting.

### 1.1. Terminology

The following terms are used throughout this document.

- **PRF**: Pseudorandom Function.
- **OPRF**: Oblivious PRF.
- **VOPRF**: Verifiable Oblivious Pseudorandom Function.
o ECVOPRF: A VOPRF built on Elliptic Curves.

o Verifier (V): Protocol initiator when computing F(k, x).

o Prover (P): Holder of secret key k.

o NIZK: Non-interactive zero knowledge.

o DLEQ: Discrete Logarithm Equality.

1.2. Requirements

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119].

2. Background

OPRFs are functionally related to RSA-based blind signature schemes, e.g., [ChaumBlindSignature]. Briefly, a blind signature scheme works as follows. Let m be a message to be signed by a server. It is assumed to be a member of the RSA group. Also, let N be the RSA modulus, and e and d be the public and private keys, respectively. A prover P and verifier V engage in the following protocol given input m.

1. V generates a random blinding element r from the RSA group, and compute m' = m^r (mod N). Send m' to the P.

2. P uses m' to compute s' = (m')^d (mod N), and sends s' to the V.

3. V removes the blinding factor r to obtain the original signature as s = (s')^(r^-1) (mod N).

By the properties of RSA, s is clearly a valid signature for m. OPRF protocols can be used to provide a symmetric equivalent to blind signatures. Essentially the client learns y = PRF(k,x) for some input x of their choice, from a server that holds k. Since the security of an OPRF means that x is hidden in the interaction, then the client can later reveal x to the server along with y.

The server can verify that y is computed correctly by recomputing the PRF on x using k. In doing so, the client provides knowledge of a 'signature' y for their value x. However, the verification procedure is symmetric since it requires knowledge of k. This is discussed more in the following section.
3. Security Properties

The security properties of an OPRF protocol with functionality $y = F(k, x)$ include those of a standard PRF. Specifically:

- Given value $x$, it is infeasible to compute $y = F(k, x)$ without knowledge of $k$.

- The output distribution of $y = F(k, x)$ is indistinguishable from the uniform distribution in the domain of the function $F$.

Additionally, we require the following additional properties:

- Non-malleable: Given $(x, y = F(k, x))$, $V$ must not be able to generate $(x', y')$ where $x' \neq x$ and $y' = F(k, x')$.

- Oblivious: $P$ must learn nothing about $V$’s input, and $V$ must learn nothing about $P$’s private key.

- Unlinkable: If $V$ reveals $x$ to $P$, $P$ cannot link $x$ to the protocol instance in which $y = F(k, x)$ was computed.

Optionally, for any protocol that satisfies the above properties, there is an additional security property:

- Verifiable: $V$ must only complete execution of the protocol if it can successfully assert that $P$ used its secret key $k$.

In practice, the notion of verifiability requires that $P$ commits to the key $k$ before the actual protocol execution takes place. Then $V$ verifies that $P$ has used $k$ in the protocol using this commitment.

4. OPRF Protocol

In this section we describe the OPRF protocol. Let $GG$ be a prime-order additive subgroup, with two distinct hash functions $H_1$ and $H_2$, where $H_1$ maps arbitrary input onto $GG$ and $H_2$ maps arbitrary input to a fixed-length output, e.g., SHA256. All hash functions in the protocol are modelled as random oracles. Let $L$ be the security parameter. Let $k$ be the prover’s ($P$) secret key, and $Y = kG$ be its corresponding ‘public key’ for some generator $G$ taken from the group $GG$. This public key is also referred to as a commitment to the key $k$. Let $x$ be the verifier’s ($V$) input to the OPRF protocol. (Commonly, it is a random $L$-bit string, though this is not required.)

The OPRF protocol begins with $V$ blinding its input for the signer such that it appears uniformly distributed $GG$. The latter then applies its secret key to the blinded value and returns the result.
To finish the computation, V then removes its blind and hashes the result using $H_2$ to yield an output. This flow is illustrated below.

```
Verifier               Prover
------------------------
| r <- $ \mathcal{G}\mathcal{G} |
| M = rH_1(x) |
```

```
M
------>
```

```
Z = kM 
[D = DLEQ_Generate(k,G,Y,M,Z)]
```

```
Z[,D] 
<------
```

```
[b = DLEQ_Verify(G,Y,M,Z,D)]
```

```
N = Zr^(-1) 
Output H_2(x, N) [if b=1, else "error"]
```

Steps that are enclosed in square brackets ($DLEQ_Generate$ and $DLEQ_Verify$) are optional for achieving verifiability. These are described in Section 5. In the verifiable mode, we assume that P has previously committed to their choice of key k with some values $(G, Y = kG)$ and these are publicly known by V. Notice that revealing $(G, Y)$ does not reveal k by the well-known hardness of the discrete log problem.

Strictly speaking, the actual PRF function that is computed is:

$$F(k, x) = N = kH_1(x)$$

It is clear that this is a PRF $H_1(x)$ maps x to a random element in $\mathcal{G}\mathcal{G}$, and $\mathcal{G}\mathcal{G}$ is cyclic. This output is computed when the client computes $Zr^(-1)$ by the commutativity of the multiplication. The client finishes the computation by outputting $H_2(x, N)$. Note that the output from P is not the PRF value because the actual input x is blinded by r.

This protocol may be decomposed into a series of steps, as described below:

- **OPRF_Setup(l):** Generate an integer k of sufficient bit-length l and output k.
- **OPRF_Blind(x):** Compute and return a blind, r, and blinded representation of x in $\mathcal{G}\mathcal{G}$, denoted M.
- **OPRF_Sign(k,M,h):** Sign input M using secret key k to produce Z, the input h is optional and equal to the cofactor of an elliptic curve. If h is not provided then it defaults to 1.
OPRF_Unblind(r,Z): Unblind blinded signature Z with blind r, yielding N and output N.

OPRF_Finalize(x,N): Finalize N to produce the output H_2(x, N).

For verifiability we modify the algorithms of VOPRF_Setup, VOPRF_Sign and VOPRF_Unblind to be the following:

VOPRF_Setup(l): Generate an integer k of sufficient bit-length l and output (k, (G,Y)) where Y = kG for some generator G in GG.

VOPRF_Sign(k,(G,Y),M,h): Sign input M using secret key k to produce Z. Generate a NIZK proof D = DLEQ_Generate(k,G,Y,M,Z), and output (Z, D). The optional cofactor h can also be provided as in OPRF_Sign.

VOPRF_Unblind(r,G,Y,M,(Z,D)): Unblind blinded signature Z with blind r, yielding N. Output N if 1 = DLEQ_Verify(G,Y,M,Z,D). Otherwise, output "error".

We leave the rest of the OPRF algorithms unmodified. When referring explicitly to VOPRF execution, we replace 'OPRF' in all method names with 'VOPRF'.

4.1. Protocol correctness

Protocol correctness requires that, for any key k, input x, and (r,M) = OPRF_Blind(x), it must be true that:

OPRF_Finalize(x, OPRF_Unblind(r,M,OPRF_Sign(k,M))) = H_2(x, F(k,x))

with overwhelming probability. Likewise, in the verifiable setting, we require that:

VOPRF_Finalize(x, VOPRF_Unblind(r,(G,Y),M,(VOPRF_Sign(k,(G,Y),M)))) = H_2(x, F(k,x))

with overwhelming probability, where (r,M) = VOPRF_Blind(x).

4.2. Instantiations of GG

As we remarked above, GG is a subgroup with associated prime-order p. While we choose to write operations in the setting where GG comes equipped with an additive operation, we could also define the operations in the multiplicative setting. In the multiplicative setting we can choose GG to be a prime-order subgroup of a finite field FF_p. For example, let p be some large prime (e.g. > 2048 bits) where p = 2q+1 for some other prime q. Then the subgroup of squares of FF_p (elements u^2 where u is an element of FF_p) is
cyclic, and we can pick a generator of this subgroup by picking \( g \) from \( \mathbb{F}_p \) (ignoring the identity element).

For practicality of the protocol, it is preferable to focus on the cases where \( GG \) is an additive subgroup so that we can instantiate the OPRF in the elliptic curve setting. This amounts to choosing \( GG \) to be a prime-order subgroup of an elliptic curve over base field \( \mathbb{GF}(p) \) for prime \( p \). There are also other settings where \( GG \) is a prime-order subgroup of an elliptic curve over a base field of non-prime order, these include the work of Ristretto [RISTRETTO] and Decaf [DECAF].

We will use \( p > 0 \) generally for constructing the base field \( \mathbb{GF}(p) \), not just those where \( p \) is prime. To reiterate, we focus only on the additive case, and so we focus only on the cases where \( \mathbb{GF}(p) \) is indeed the base field.

### 4.3. OPRF algorithms

This section provides algorithms for each step in the OPRF protocol. We describe the VOPRF analogues in Section 4.4. We provide generic utility algorithms in Section 4.5.

1. \( P \) samples a uniformly random key \( k \leftarrow \{0,1\}^l \) for sufficient length \( l \), and interprets it as an integer.

2. \( V \) computes \( X = H_1(x) \) and a random element \( r \) (blinding factor) from \( \mathbb{GF}(p) \), and computes \( M = rX \).

3. \( V \) sends \( M \) to \( P \).

4. \( P \) computes \( Z = kM = rkX \).

5. In the elliptic curve setting, \( P \) multiplies \( Z \) by the cofactor (denoted \( h \)) of the elliptic curve.

6. \( P \) sends \( Z \) to \( V \).

7. \( V \) unblinds \( Z \) to compute \( N = r^{(-1)}Z = kX \).

8. \( V \) outputs the pair \( H_2(x, N) \).

#### 4.3.1. OPRF_Setup
Input:

l: Some suitable choice of key-length (e.g. as described in {{NIST}}).

Output:

k: A key chosen from \((0,1)^l\) and interpreted as an integer value.

Steps:

1. Sample \(k_{\text{bin}} \leftarrow \{0,1\}^l\)
2. Output \(k \leftarrow \text{bin2scalar}(k_{\text{bin}}, l)\)

4.3.2. OPRF_Blind

Input:

x: V’s PRF input.

Output:

r: Random scalar in \([1, p - 1]\).
M: Blinded representation of x using blind r, an element in GG.

Steps:

1. \(r \leftarrow \text{GF}(p)\)
2. \(M := rH_1(x)\)
3. Output \((r, M)\)

4.3.3. OPRF_Sign

Input:

k: Signer secret key.
M: An element in GG.
h: optional cofactor (defaults to 1).

Output:

Z: Scalar multiplication of the point M by k, element in GG.

Steps:

1. \(Z := kM\)
2. \(Z \leftarrow hZ\)
3. Output Z
4.3.4. OPRF_Unblind

Input:

r: Random scalar in \([1, p - 1]\).
Z: An element in GG.

Output:

N: Unblinded signature, element in GG.

Steps:

1. \(N := (1/r)Z\)
2. Output \(N\)

4.3.5. OPRF_Finalize

Input:

x: PRF input string.
N: An element in GG.

Output:

y: Random element in \(\{0,1\}^L\).

Steps:

1. \(y := H_2(x, N)\)
2. Output \(y\)

4.4. VOPRF algorithms

The steps in the VOPRF setting are written as:

1. \(P\) samples a uniformly random key \(k \leftarrow \{0,1\}^l\) for sufficient length \(l\), and interprets it as an integer.

2. \(P\) commits to \(k\) by computing \((G,Y)\) for \(Y=kG\) and where \(G\) is a generator of GG. \(P\) makes \((G,Y)\) publicly available.

3. \(V\) computes \(X = H_1(x)\) and a random element \(r\) (blinding factor) from GF(p), and computes \(M = rX\).

4. \(V\) sends \(M\) to \(P\).

5. \(P\) computes \(Z = kM = rkX\), and \(D = \text{DLEQ\_Generate}(k,G,Y,M,Z)\).
6. P sends (Z, D) to V.

8. V unblinds Z to compute N = r^(-1)Z = kX.

9. V outputs the pair H_2(x, N).

4.4.1. VOPRF_Setup

Input:

G: Public generator of GG.
l: Some suitable choice of key-length (e.g. as described in {{NIST}}).

Output:

k: A key chosen from \{0,1\}^l and interpreted as an integer value.
(G,Y): A pair of curve points, where Y=kG.

Steps:

1. k <- OPRF_Setup(l)
2. Y := kG
3. Output (k, (G,Y))

4.4.2. VOPRF_Blind

Input:

x: V’s PRF input.

Output:

r: Random scalar in [1, p - 1].
M: Blinded representation of x using blind r, an element in GG.

Steps:

1. r <- $ GF(p)
2. M := rH_1(x)
3. Output (r, M)
4.4.3. VOPRF_Sign

Input:

- k: Signer secret key.
- G: Public generator of group GG.
- Y: Signer public key (= kG).
- M: An element in GG.
- h: optional cofactor (defaults to 1).

Output:

- Z: Scalar multiplication of the point M by k, element in GG.
- D: DLEQ proof that log_G(Y) == log_M(Z).

Steps:

1. Z := kM
2. Z <- hZ
3. D = DLEQ_Generate(k, G, Y, M, Z)
4. Output (Z, D)

4.4.4. VOPRF_Unblind

Input:

- r: Random scalar in [1, p - 1].
- G: Public generator of group GG.
- Y: Signer public key.
- M: Blinded representation of x using blind r, an element in GG.
- Z: An element in GG.
- D: D = DLEQ_Generate(k, G, Y, M, Z).

Output:

- N: Unblinded signature, element in GG.

Steps:

1. N := (1/r)Z
2. If 1 = DLEQ_Verify(G, Y, M, Z, D), output N
3. Output "error"

4.4.5. VOPRF_Finalize
Input:

x: PRF input string.
N: An element in GG, or "error".

Output:

y: Random element in \(\{0,1\}^L\), or "error"

Steps:

1. If \(N == \text{"error"}\), output "error".
2. \(y := H_2(x, N)\)
3. Output \(y\)

4.5. Utility algorithms

4.5.1. bin2scalar

This algorithm converts a binary string to an integer modulo \(p\).

Input:

s: binary string (little-endian)
l: length of binary string
p: modulus

Output:

z: An integer modulo \(p\)

Steps:

1. \(s\text{Vec} \leftarrow \text{vec}(s)\) (converts \(s\) to a column vector of dimension \(l\))
2. \(p2\text{Vec} \leftarrow (2^0, 2^1, ..., 2^{(l-1)})\) (row vector of dimension \(l\))
3. \(z \leftarrow p2\text{Vec} \times s\text{Vec} \mod p\)
4. Output \(z\)

4.6. Efficiency gains with pre-processing and additive blinding

In the [OPAQUE] draft, it is noted that it may be more efficient to use additive blinding rather than multiplicative if the client can preprocess some values. For example, computing \(rH_1(x)\) is an example of multiplicative blinding. A valid way of computing additive blinding would be to instead compute \(H_1(x) + rG\), where \(G\) is the common generator for the group.
If the client preprocesses values of the form \( rG \), then computing \( H_1(x) + rG \) is more efficient than computing \( rH_1(x) \) (one addition against \( \log_2(r) \)). Therefore, it may be advantageous to define the OPRF and VOPRF protocols using additive blinding rather than multiplicative blinding. In fact the only algorithms that need to change are OPRF_Blind and OPRF_Unblind (and similarly for the VOPRF variants).

We define the additive blinding variants of the above algorithms below along with a new algorithm OPRF_Preprocess that defines how preprocessing is carried out. The equivalent algorithms for VOPRF are almost identical and so we do not redefine them here. Notice that the only computation that changes is for \( V \), the necessary computation of \( P \) does not change.

### 4.6.1. OPRF_Preprocess

**Input:**

- \( G \): Public generator of GG

**Output:**

- \( r \): Random scalar in \([1, p-1]\)
- \( rG \): An element in GG.
- \( rY \): An element in GG.

**Steps:**

1. \( r \leftarrow \text{GF}(p) \)
2. Output \((r, rG, rY)\)

### 4.6.2. OPRF_Blind

**Input:**

- \( x \): V’s PRF input.
- \( rG \): Preprocessed element of GG.

**Output:**

- \( M \): Blinded representation of \( x \) using blind \( r \), an element in GG.

**Steps:**

1. \( M := H_1(x) + rG \)
2. Output \( M \)
4.6.3. OPRF_Unblind

Input:

rY: Preprocessed element of GG.
M: Blinded representation of x using rG, an element in GG.
Z: An element in GG.

Output:

N: Unblinded signature, element in GG.

Steps:

1. N := Z-rY
2. Output N

Notice that OPRF_Unblind computes (Z-rY) = k(H_1(x)+rG) - rkG = kH_1(x) by the commutativity of scalar multiplication in GG. This is the same output as in the original OPRF_Unblind algorithm.

5. NIZK Discrete Logarithm Equality Proof

For the VOPRF protocol we require that V is able to verify that P has used its private key k to evaluate the PRF. We can do this by showing that the original commitment (G,Y) output by VOPRF_Setup(l) satisfies log_G(Y) == log_M(Z) where Z is the output of VOPRF_Sign(k,(G,Y),M).

This may be used, for example, to ensure that P uses the same private key for computing the VOPRF output and does not attempt to "tag" individual verifiers with select keys. This proof must not reveal the P’s long-term private key to V.

Consequently, this allows extending the OPRF protocol with a (non-interactive) discrete logarithm equality (DLEQ) algorithm built on a Chaum-Pedersen [ChaumPedersen] proof. This proof is divided into two procedures: DLEQ_Generate and DLEQ_Verify. These are specified below.

5.1. DLEQ_Generate
Input:

- **k**: Signer secret key.
- **G**: Public generator of GG.
- **Y**: Signer public key (= kG).
- **M**: An element in GG.
- **Z**: An element in GG.
- **H_3**: A hash function from GG to \( \{0,1\}^L \), modelled as a random oracle.

Output:

- **D**: DLEQ proof \((c, s)\).

Steps:

1. \( r \leftarrow \$ GF(p) \)
2. \( A := rG \) and \( B := rM \).
3. \( c \leftarrow H_3(G,Y,M,Z,A,B) \)
4. \( s := (r - ck) \mod p \)
5. Output \( D := (c, s) \)

5.2. **DLEQ Verify**

Input:

- **G**: Public generator of GG.
- **Y**: Signer public key.
- **M**: An element in GG.
- **Z**: An element in GG.
- **D**: DLEQ proof \((c, s)\).

Output:

True if \( \log_G(Y) == \log_M(Z) \), False otherwise.

Steps:

1. \( A' := (sG + cY) \)
2. \( B' := (sM + cZ) \)
3. \( c' \leftarrow H_3(G,Y,M,Z,A',B') \)
4. Output \( c == c' \)

6. **Batched VOPRF evaluation**

Common applications (e.g. [PrivacyPass]) require V to obtain multiple PRF evaluations from P. In the VOPRF case, this would also require generation and verification of a DLEQ proof for each \( Z_i \) received by V. This is costly, both in terms of computation and...
communication. To get around this, applications use a ‘batching’
procedure for generating and verifying DLEQ proofs for a finite
number of PRF evaluation pairs \((M_i, Z_i)\). For \(n\) PRF evaluations:

- Proof generation is slightly more expensive from 2\(n\) modular
  exponentiations to 2\(n+2\).
- Proof verification is much more efficient, from 4\(m\) modular
  exponentiations to 2\(n+4\).
- Communications falls from 2\(n\) to 2 group elements.

Therefore, since \(P\) is usually a powerful server, we can tolerate a
slight increase in proof generation complexity for much more
efficient communication and proof verification.

In this section, we describe algorithms for batching the DLEQ
generation and verification procedure. For these algorithms we
require a pseudorandom generator PRNG: \(\{0,1\}^a \times \mathbb{Z} \rightarrow \{(0,1)^b\}^n\)
that takes a seed of length \(a\) and an integer \(n\) as input, and outputs
\(n\) elements in \(\{0,1\}^b\).

### 6.1. Batched DLEQ algorithms

#### 6.1.1. Batched_DLEQGenerate
Input:

k: Signer secret key.
G: Public generator of group GG.
Y: Signer public key (= kG).
n: Number of PRF evaluations.
{Mi}: An array of points in GG of length n.
{Zi}: An array of points in GG of length n.
PRNG: A pseudorandom generator of the form above.
salt: An integer salt value for each PRNG invocation
info: A string value for splitting the domain of the PRNG
H_4: A hash function from GG^(2n+2) to {0,1}^a, modelled as a random oracle.

Output:

D: DLEQ proof (c, s).

Steps:

1. seed <- H_4(G,Y, {Mi,Zi})
2. d1,...dn <- PRNG(seed, salt, info, n)
3. c1,...,cn := (int)d1,...,(int)dn
4. M := c1M1 + ... + cnMn
5. Z := c1Z1 + ... + cnZn
6. Output D <- DLEQ_Generate(k, G, Y, M, Z)

6.1.2. Batched_DLEQ_Verify

Input:

G: Public generator of group GG.
Y: Signer public key.
{Mi}: An array of points in GG of length n.
{Zi}: An array of points in GG of length n.
D: DLEQ proof (c, s).

Output:

True if log_G(Y) == log_(Mi)(Zi) for each i in 1...n, False otherwise.

Steps:

1. seed <- H_4(G,Y, {Mi,Zi})
2. d1,...dn <- PRNG(seed, salt, info, n)
3. c1,...,cn := (int)d1,...,(int)dn
4. M := c1M1 + ... + cnMn
5. Z := c1Z1 + ... + cnZn
6. Output DLEQ_Verify(G,Y,M,Z,D)
6.2. Modified protocol execution

The VOPRF protocol from Section 4 changes to allow specifying multiple blinded PRF inputs \([Mi]\) for \(i \in 1...n\). Then \(P\) computes the array \([Zi]\) and replaces DLEQ_Generate with Batched_DLEQ_Generate over these arrays. The same applies to the algorithm VOPRF_Sign. The same applies for replacing DLEQ_Verify with Batched_DLEQ_Verify when \(V\) verifies the response from \(P\) and during the algorithm VOPRF_Verify.

6.3. PRNG and resampling

Any function that satisfies the security properties of a pseudorandom number generator can be used for computing the batched DLEQ proof. For example, SHAKE-256 [SHAKE] or HKDF-SHA256 [RFC5869] would be reasonable choices for groups that have an order of 256 bits.

We note that the PRNG outputs \(d1,...,dn\) must be smaller than the order of the group/curve that is being used. Resampling can be achieved by increasing the value of the iterator that is used in the info field of the PRNG input.

7. Supported ciphersuites

This section specifies supported ECVOPRF group and hash function instantiations. We only provide ciphersuites in the EC setting as these provide the most efficient way of instantiating the OPRF. Our instantiation includes considerations for providing the DLEQ proofs that make the instantiation a VOPRF. Supporting OPRF operations (ECOPRF) alone can be allowed by simply dropping the relevant components. In addition, we currently only support ciphersuites demonstrating 128 bits of security.

7.1. ECVOPRF-P256-HKDF-SHA256-SSWU:

- GG: SECP256K1 curve [SEC2]

- \(H_1\): H2C-P256-SHA256-SSWU- [I-D.irtf-cfrg-hash-to-curve]

* label: voprf_h2c

- \(H_2\): SHA256

- \(H_3\): SHA256

- \(H_4\): SHA256

- PRNG: HKDF-SHA256
7.2. ECVOPRF-RISTRETTO-HKDF-SHA512-Elligator2:

- GG: Ristretto [RISTRETTO]
  - H_1: H2C-Curve25519-SHA512-Elligator2-Clear [I-D.irtf-cfrg-hash-to-curve]
    * label: voprf_h2c
  - H_2: SHA512
  - H_3: SHA512
  - H_4: SHA512
- PRNG: HKDF-SHA512

In the case of Ristretto, internal point representations are represented by Ed25519 [RFC7748] points. As a result, we can use the same hash-to-curve encoding as we would use for Ed25519 [I-D.irtf-cfrg-hash-to-curve]. We remark that the ‘label’ field is necessary for domain separation of the hash-to-curve functionality.

8. Security Considerations

Security of the protocol depends on P’s secrecy of k. Best practices recommend P regularly rotate k so as to keep its window of compromise small. Moreover, it each key should be generated from a source of safe, cryptographic randomness.

Another critical aspect of this protocol is reliance on [I-D.irtf-cfrg-hash-to-curve] for mapping arbitrary inputs x to points on a curve. Security requires this mapping be pre-image and collision resistant.

8.1. Timing Leaks

To ensure no information is leaked during protocol execution, all operations that use secret data MUST be constant time. Operations that SHOULD be constant time include: H_1() (hashing arbitrary strings to curves) and DLEQ_Generate(). [I-D.irtf-cfrg-hash-to-curve] describes various algorithms for constant-time implementations of H_1.
8.2. Hashing to curves

We choose different encodings in relation to the elliptic curve that is used, all methods are illuminated precisely in [I-D.irtf-cfrg-hash-to-curve]. In summary, we use the simplified Shallue-Woestijne-Ulas algorithm for hashing binary strings to the P-256 curve; the Icart algorithm for hashing binary strings to P384; the Elligator2 algorithm for hashing binary strings to CURVE25519 and CURVE448.

8.3. Verifiability (key consistency)

DLEQ proofs are essential to the protocol to allow V to check that P’s designated private key was used in the computation. A side effect of this property is that it prevents P from using a unique key for select verifiers as a way of "tagging" them. If all verifiers expect use of a certain private key, e.g., by locating P’s public key published from a trusted registry, then P cannot present unique keys to an individual verifier.

For this side effect to hold, P must also be prevented from using other techniques to manipulate their public key within the trusted registry to reduce client anonymity. For example, if P’s public key is rotated too frequently then this may stratify the user base into small anonymity groups (those with VOPRF_Sign outputs taken from a given key epoch). In this case, it may become practical to link VOPRF sessions for a given user and thus compromises their privacy.

Similarly, if P can publish N public keys to a trusted registry then P may be able to control presentation of these keys in such a way that V is retroactively identified by V’s key choice across multiple requests.

9. Applications

This section describes various applications of the VOPRF protocol.

9.1. Privacy Pass

This VOPRF protocol is used by Privacy Pass system to help Tor users bypass CAPTCHA challenges. Their system works as follows. Client C connects - through Tor - to an edge server E serving content. Upon receipt, E serves a CAPTCHA to C, who then solves the CAPTCHA and supplies, in response, n blinded points. E verifies the CAPTCHA response and, if valid, signs (at most) n blinded points, which are then returned to C along with a batched DLEQ proof. C stores the tokens if the batched proof verifies correctly. When C attempts to connect to E again and is prompted with a CAPTCHA, C uses one of the
unblinded and signed points, or tokens, to derive a shared symmetric key sk used to MAC the CAPTCHA challenge. C sends the CAPTCHA, MAC, and token input x to E, who can use x to derive sk and verify the CAPTCHA MAC. Thus, each token is used at most once by the system.

The Privacy Pass implementation uses the P-256 instantiation of the VOPRF protocol. For more details, see [DGSTV18].

9.2. Private Password Checker

In this application, let D be a collection of plaintext passwords obtained by prover P. For each password p in D, P computes VOPRF_Sign on H_1(p), where H_1 is as described above, and stores the result in a separate collection D’ . P then publishes D’ with Y, its public key. If a client C wishes to query D’ for a password p’, it runs the VOPRF protocol using p as input x to obtain output y. By construction, y will be the signature of p hashed onto the curve. C can then search D’ for y to determine if there is a match.

Examples of such password checkers already exist, for example: [JKXX16], [JKK14] and [SJKS17].

9.2.1. Parameter Commitments

For some applications, it may be desirable for P to bind tokens to certain parameters, e.g., protocol versions, ciphersuites, etc. To accomplish this, P should use a distinct scalar for each parameter combination. Upon redemption of a token T from V, P can later verify that T was generated using the scalar associated with the corresponding parameters.

10. Acknowledgements

This document resulted from the work of the Privacy Pass team [PrivacyPass]. The authors would also like to acknowledge the helpful conversations with Hugo Krawczyk. Eli-Shaoul Khedouri provided additional review and comments on key consistency.
