IPv6 Neighbor Discovery on Wireless Networks
draft-thubert-6man-ipv6-over-wireless-04

Abstract

This document describes how the original IPv6 Neighbor Discovery and Wireless ND (WiND) can be applied on various abstractions of wireless media.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at https://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on March 29, 2020.

1. Introduction

IEEE STD. 802.1 [IEEEstd8021] Ethernet Bridging provides an efficient and reliable broadcast service for wired networks; applications and protocols have been built that heavily depend on that feature for their core operation. Unfortunately, Low-Power Lossy Networks (LLNs) and local wireless networks generally do not provide the broadcast capabilities of Ethernet Bridging in an economical fashion.

As a result, protocols designed for bridged networks that rely on multicast and broadcast often exhibit disappointing behaviours when employed unmodified on a local wireless medium (see [I-D.ietf-mboned-ieee802-mcast-problems]).

Wi-Fi [IEEEstd80211] Access Points (APs) deployed in an Extended Service Set (ESS) act as Ethernet Bridges [IEEEstd8021], with the property that the bridging state is established at the time of association. This ensures connectivity to the node (STA) and protects the wireless medium against broadcast-intensive Transparent Bridging reactive Lookups.
In other words, the association process is used to register the MAC Address of the STA to the AP. The AP subsequently proxies the bridging operation and does not need to forward the broadcast Lookups over the radio.

Like Transparent Bridging, IPv6 [RFC8200] Neighbor Discovery [RFC4861] [RFC4862] Protocol (IPv6 ND) is a reactive protocol, based on multicast transmissions to locate an on-link correspondent and ensure the uniqueness of an IPv6 address. The mechanism for Duplicate Address Detection (DAD) [RFC4862] was designed for the efficient broadcast operation of Ethernet Bridging. Since broadcast can be unreliable over wireless media, DAD often fails to discover duplications [I-D.yourtchenko-6man-dad-issues]. In practice, IPv6 addresses very rarely conflict because of the entropy of the 64-bit Interface IDs, not because address duplications are detected and resolved.

The IPv6 ND Neighbor Solicitation (NS) [RFC4861] message is used for DAD and Address Resolution (AR) when a node moves, or wakes up and reconnects to the wireless network. The NS message is targeted to a Solicited-Node Multicast Address (SNMA) [RFC4291] and should in theory only reach a very small group of nodes. It must be noted that in the case of Ethernet LANs as well as most WLANs and LPWANs, the Layer-3 multicast operation becomes a MAC_Layer broadcast for the lack of a Layer-2 multicast operation that could handle a possibly very large number of groups in order to make the unicast efficient. It results that IPv6 ND messages are processed by most of the wireless nodes over the subnet (e.g., the ESS fabric) regardless of how few of the nodes are subscribed to the SNMA.

IPv6 ND address Lookups and DADs over a large fabric can generate hundreds of broadcasts per second. If the broadcasts were blindly copied over Wi-Fi and/or over a LowPower Lossy Network (LLN), the ND-related multicast could consume enough bandwidth to cause a substantial degradation to the unicast traffic service [I-D.vyncke-6man-mcast-not-efficient]. To protect their bandwidth, some networks throttle ND-related broadcasts, which reduces the capability of the protocol to perform as expected.

Conversely, a Wi-Fi station must keep its radio turned on to listen to the periodic series of broadcast frames, which for the most part will be dropped when they reach Layer-3. In order to avoid this waste of energy and increase its battery life, a typical battery-operated device such as an IoT sensor or a smartphone will blindly ignore a ratio of the broadcasts, making IPv6 ND operations even less reliable.
These problems can be alleviated by reducing the IPv6 ND broadcasts over wireless access links. This has been done by splitting the broadcast domains and by routing between subnets, at the extreme by assigning a /64 prefix to each wireless node (see [RFC8273]).

Another way is to proxy at the boundary of the wired and wireless domains the Layer-3 protocols that rely on MAC Layer broadcast operations. For instance, IEEE 802.11 [IEEEstd80211] situates proxy-ARP (IPv4) and proxy-ND (IPv6) functions at the Access Points (APs).

But proxying ND requires a perfect knowledge of the peer IPv6 addresses for which proxying is provided. In a generic fashion, radio connectivity changes with movements and variations in the environment, which makes forming and maintaining that knowledge a hard problem in the general case.

Discovering peer addresses by snooping the IPv6 ND protocol as proposed for SAVI [I-D.bi-savi-wlan] was found to be unreliable. An IPv6 address may not be discovered immediately due to a packet loss, or if a "silent" node is not currently using one of its addresses, e.g., a node that waits in wake-on-lan state. A change of state, e.g. due to a movement, may be missed or misordered, leading to unreliable connectivity and an incomplete knowledge of the set of peers.

Wireless ND (WiND) introduces a new approach to IPv6 ND that is designed to apply to the WLANs and WPANs types of networks. On the one hand, WiND avoids the use of broadcast operation for DAD and AR, and on the other hand, WiND supports use cases where Subnet and MAC-level domains are not congruent, which is common in those types of networks unless a specific MAC-Level emulation is provided. WiND applies routing inside the Subnets, which enables MultiLink Subnets. Hosts register their addresses to their serving routers with [RFC8505]. With the registration, routers have a complete knowledge of the hosts they serve and in return, hosts obtain routing services for their registered addresses. The registration is abstract to the routing protocol, and it can be protected to prevent impersonation attacks with [I-D.ietf-6lo-ap-nd].

The routing service can be a simple reflexion in a Hub-and-Spoke Subnet that emulates an IEEE Std 802.11 Infrastructure BSS at Layer 3. It can also be a full-fledge routing protocol, in particular RPL [RFC6550] that was designed to adapt to various LLNs such as WLAN and WPAN radio meshes with the concept of Objective Function. Finally, the routing service can also be ND proxy that emulates an IEEE Std 802.11 Infrastructure ESS at Layer 3. WiND specifies the IPv6 Backbone Router for that purpose in [I-D.ietf-6lo-backbone-router]. More details on WiND can be found in Section 4.1.
2. Acronyms

This document uses the following abbreviations:

6BBR: 6LoWPAN Backbone Router

6LBR: 6LoWPAN Border Router

6LN: 6LoWPAN Node

6LR: 6LoWPAN Router

ARO: Address Registration Option

DAC: Duplicate Address Confirmation

DAD: Duplicate Address Detection

DAR: Duplicate Address Request

EDAC: Extended Duplicate Address Confirmation

EDAR: Extended Duplicate Address Request

MLSN: Multi-Link Subnet

LLN: Low-Power and Lossy Network

NA: Neighbor Advertisement

NBMA: Non-Broadcast Multi-Access

NCE: Neighbor Cache Entry

ND: Neighbor Discovery

NDP: Neighbor Discovery Protocol

NS: Neighbor Solicitation

RPL: IPv6 Routing Protocol for LLNs

RA: Router Advertisement

RS: Router Solicitation

WiND: Wireless Neighbor Discovery
3. IP Models

3.1. Physical Broadcast Domain

At the physical (PHY) Layer, a broadcast domain is the set of nodes that may receive a datagram that one sends over an interface, in other words the set of nodes in range of radio transmission. This set can comprise a single peer on a serial cable used as point-to-point (P2P) link. It may also comprise multiple peer nodes on a broadcast radio or a shared physical resource such as the legacy Ethernet shared wire.

On WLAN and WPAN radios, the physical broadcast domain is defined by a particular transmitter, as the set of nodes that can receive what this transmitter is sending. Literally every datagram defines its own broadcast domain since the chances of reception of a given datagram are statistical. In average and in stable conditions, the broadcast domain of a particular node can be still be seen as mostly constant and can be used to define a closure of nodes on which an upper-layer abstraction can be built.

A PHY-layer communication can be established between 2 nodes if their physical broadcast domains overlap.

On WLAN and WPAN radios, this property is usually reflexive, meaning that if B can receive a datagram from A, then A can receive a datagram from B. But there can be asymmetries due to power levels, interferers near one of the receivers, or differences in the quality of the hardware (e.g., crystals, PAs and antennas) that may affect the balance to the point that the connectivity becomes mostly unidirectional, e.g., A to B but practically not B to A. It takes a particular effort to place a set of devices in a fashion that all their physical broadcast domains fully overlap, and it can not be assumed in the general case. In other words, the property of radio connectivity is generally not transitive, meaning that A may be in range with B and B may be in range with C does not necessarily imply that A is in range with C.

We define Direct MAC-Layer Broadcast (DMC) a transmission mode where the broadcast domain that is usable at the MAC layer is directly the physical broadcast domain. IEEE 802.15.4 [IEEE802154] and IEEE 802.11 OCB [IEEEstd80211] (for Out of the Context of a BSS) are examples of DMC radios. This contrasts with a number of MAC-layer Broadcast Emulation schemes that are described in the next section.
3.2. MAC-Layer Broadcast Emulations

While a physical broadcast domain is constrained to a single shared wire, Ethernet Bridging emulates the broadcast properties of that wire over a whole physical mesh of Ethernet links. For the upper layer, the qualities of the shared wire are essentially conserved, with a reliable and cheap broadcast operation over a closure of nodes defined by their connectivity to the emulated wire.

In large switched fabrics, overlay techniques enable a limited connectivity between nodes that are known to a mapping server. The emulated broadcast domain is configured to the system, e.g., with a VXLAN network identifier (VNID). Broadcast operations on the overlay can be emulated but can become very expensive, and it makes sense to proactively install the relevant state in the mapping server as opposed to rely on reactive broadcast lookups.

An IEEE Std 802.11 Infrastructure Basic Service Set (BSS) also provides a closure of nodes as defined by the broadcast domain of a central Access Point (AP). The AP relays both unicast and broadcast packets and ensures a reflexive and transitive emulation of the shared wire between the associated nodes, with the capability to signal link-up/link-down to the upper layer. Within an Infrastructure BSS, the physical broadcast domain of the AP serves as emulated broadcast domain for all the nodes that are associated to the AP. Broadcast packets are relayed by the AP and are not acknowledged. To ensure that all nodes in the BSS receive the broadcast transmission, AP transmits at the slowest PHY speed. This translates into maximum co-channel interferences for others and longest occupancy of the medium, for a duration that can be 100 times that of a unicast. For that reason, upper layer protocols should tend to avoid the use of broadcast when operating over Wi-Fi.

In an IEEE Std 802.11 Infrastructure Extended Service Set (ESS), infrastructure BSSes are interconnected by a bridged network, typically running Transparent Bridging and Spanning tree Protocol. In the original model of learning bridges, the state in the Transparent Bridge is set by observing the source MAC address of the frames. When a state is missing for a destination MAC address, the frame is broadcasted with the expectation that the response will populate the state. This is a reactive operation, meaning that the state is populated reactively to a need for forwarding. It is also possible in the original model to send a gratuitous frame to advertise self throughout the bridged network, and that is also a broadcast.

In contrast, the process of the Wi-Fi association prepares a bridging state proactively at the AP, which avoids the need for a reactive
broadcast lookup over the wireless access. The AP may also generate a gratuitous broadcast sourced at the MAC address of the STA to prepare or update the state in the learning bridges so they point towards the AP for the MAC address of the STA. With WiND, IPv6 ND evolves towards similar proactive methods at Layer-3 for its operation of address discovery (AD) and duplicate address detection (DAD).

In some cases of WLAN and WPAN radios, a mesh-under technology (e.g., a IEEE 802.11s or IEEE 802.15.10) provides meshing services that are similar to bridging, and the broadcast domain is well defined by the membership of the mesh. Mesh-Under emulates a broadcast domain by flooding the broadcast packets at Layer-2. When operating on a single frequency, this operation is known to interfere with itself, forcing deployment to introduce delays that dampen the collisions. All in all, the mechanism is slow, inefficient and expensive.  

Going down the list of cases above, the cost of a broadcast transmissions becomes increasingly expensive, and there is a push to rethink the upper-layer protocols so as to reduce the dependency on broadcast operations.

There again, a MAC-layer communication can be established between 2 nodes if their MAC-layer broadcast domains overlap. In the absence of a MAC-layer emulation such as a mesh-under or an Infrastructure BSS, the MAC-layer broadcast domain is congruent with that of the PHY-layer and inherits its properties for reflexivity and transitivity. IEEE 802.11 OCB, which operates Out of the Context of a BSS (DMC radios) is an example of a network that does not have a MAC-Layer broadcast domain emulation, which means that it will exhibit mostly reflexive and mostly non-transitive transmission properties.

3.3. Mapping the IPv6 Link Abstraction

IPv6 defines a concept of Link, Link Scope and Link-Local Addresses (LLA), an LLA being unique and usable only within the Scope of a Link. The IPv6 Neighbor Discovery (ND) [RFC4861][RFC4862] Duplicate Address Detection (DAD) process leverages a multicast transmission to ensure that an IPv6 address is unique as long as the owner of the address is connected to the broadcast domain. It must be noted that in all the cases in this specification, the Layer-3 multicast operation is always a MAC_Layer broadcast for the lack of a Layer-2 multicast operation that could handle a possibly very large number of groups in order to make the unicast efficient. This means that for every multicast packet regardless of the destination group, all nodes will receive the packet and process it all the way to Layer-3.
On wired media, the Link is often confused with the physical broadcast domain because both are determined by the serial cable or the Ethernet shared wire. Ethernet Bridging reinforces that illusion by provising a MAC-Layer broadcast domain that emulates a physical broadcast domain over the mesh of wires. But the difference shows on legacy Non-Broadcast Multi-Access (NBMA) such as ATM and Frame-Relay, on shared links and on newer types of NBMA networks such as radio and composite radio-wires networks. It also shows when private VLANs or Layer-2 cryptography restrict the capability to read a frame to a subset of the connected nodes.

In mesh-under and Infrastructure BSS, the IP Link extends beyond the physical broadcast domain to the emulated MAC-Layer broadcast domain. Relying on Multicast for the ND operation remains feasible but becomes detrimental to unicast traffic, energy-inefficient and unreliable, and its use is discouraged.

On DMC radios, IP Links between peers come and go as the individual physical broadcast domains of the transmitters meet and overlap. The DAD operation cannot provide once and for all guarantees on the broadcast domain defined by one radio transmitter if that transmitter keeps meeting new peers on the go. The nodes may need to form new LLAs to talk to one another and the scope where LLA uniqueness can be dynamically checked is that pair of nodes. As long as there’s no conflict a node may use the same LLA with multiple peers but it has to revalidate DAD with every new peer node. In practice, each pair of nodes defines a temporary P2P link, which can be modeled as a sub-interface of the radio interface.

3.4. Mapping the IPv6 Subnet Abstraction

IPv6 also defines a concept of Subnet for Glocal and Unique Local Addresses. Addresses in a same Subnet share a same prefix and by extension, a node belongs to a Subnet if it has an interface with an address on that Subnet. A Subnet prefix is Globally Unique so it is sufficient to validate that an address that is formed from a Subnet prefix is unique within that Subnet to guarantee that it is globally unique. IPv6 aggregation relies on the property that a packet from the outside of a Subnet can be routed to any router that belongs to the Subnet, and that this router will be able to either resolve the destination MAC address and deliver the packet, or route the packet to the destination within the Subnet. If the Subnet is known as onlink, then any node may also resolve the destination MAC address and deliver the packet, but if the Subnet is not onlink, then a host that does not have an NCE for the destination will need to pass the packet to a router.
On IEEE Std. 802.3, a Subnet is often congruent with an IP Link because both are determined by the physical attachment to an Ethernet shared wire or an IEEE Std. 802.1 bridged broadcast domain. In that case, the connectivity over the Link is transitive, the Subnet can appear as onlink, and any node can resolve a destination MAC address of any other node directly using IPv6 Neighbor Discovery.

But an IP Link and an IP Subnet are not always congruent. In a shared Link situation, a Subnet may encompass only a subset of the nodes connected to the Link. In Route-Over Multi-Link Subnets (MLSN) [RFC4903], routers federate the Links between nodes that belong to the Subnet, the Subnet is not onlink and it extends beyond any of the federated Links.

The DAD and lookup procedures in IPv6 ND expects that a node in a Subnet is reachable within the broadcast domain of any other node in the Subnet when that other node attempts to form an address that would be a duplicate or attempts to resolve the MAC address of this node. This is why ND is only applicable for P2P and transit links, and requires extensions for other topologies.

4. Wireless ND

4.1. Introduction to WiND

Wireless Neighbor Discovery (WiND) [RFC6775][RFC8505][I-D.ietf-6lo-backbone-router][I-D.ietf-6lo-ap-nd] defines a new ND operation that is based on 2 major paradigm changes, pro-active address registration by hosts to their attachment routers and routing to host routes (/128) within the subnet. This allows WiND to avoid the classical ND expectations of transit links and Subnet-wide broadcast domains.

The pro-active address registration is performed with a new option in NS/NA messages, the Extended Address Registration Option (EARO) defined in [RFC8505]. This method allows to prepare and maintain the host routes in the routers and avoids the reactive NS(Lookup) found in IPv6 ND. This is a direct benefit for wireless Links since it avoids the MAC level broadcasts that are associated to NS(Lookup).

The EARO provides information to the router that is independent to the routing protocol and routing can take multiple forms, from a traditional IGP to a collapsed ub-and-Spoke model where only one router owns and advertises the prefix. [RFC8505] is already referenced for RIFT [I-D.ietf-rift-rift], RPL [RFC6550] with [I-D.thubert-roll-unaware-leaves] and IPv6 ND proxy [I-D.ietf-6lo-backbone-router].
WiND does not change IPv6 addressing [RFC4291] or the current practices of assigning prefixes to subnets. It is still typical to assign a /64 to a subnet and to use interface IDs of 64 bits. Duplicate Address detection within the Subnet is performed with a central registrar, using new ND Extended Duplicate Address messages (EDAR and EDAC) [RFC8505]. This operation modernizes ND for application in overlays with Map Resolvers and enables unicast lookups [I-D.thubert-6lo-unicast-lookup] for addresses registered to the resolver.

WiND also enables to extend a legacy /64 on Ethernet with ND proxy over the wireless. This way nodes can form any address the want and move freely from an L3-AP (that is really a backbone router in bridging mode, more in [I-D.ietf-6lo-backbone-router]) to another, without renumbering. Backbone Routers federate multiple LLNs over a Backbone Link to form a Multilink Subnet (MLSN). Backbone Routers placed along the LLN edge of the Backbone handle IPv6 Neighbor Discovery, and forward packets on behalf of registered nodes.

An LLN node (6LN) registers all its IPv6 Addresses using an NS(EARO) as specified in [RFC8505] to the 6BBR. The 6BBR is also a Border Router that performs IPv6 Neighbor Discovery (IPv6 ND) operations on its Backbone interface on behalf of the 6LNs that have registered addresses on its LLN interfaces without the need of a broadcast over the wireless medium.

WiND is also compatible with DHCPv6 and other forms of address assignment in which case it can still be used for DAD.

4.2. Links and Link-Local Addresses

For Link-Local Addresses, DAD is performed between communicating pairs of nodes. It is carried out as part of a registration process that is based on a NS/NA exchange that transports an EARO. During that process, the DAD is validated and a Neighbor Cache Entry (NCE) is populated with a single unicast exchange.

For instance, in the case of a Bluetooth Low Energy (BLE) [RFC7668][IEEEstd802151] Hub-and Spoke configuration, Uniqueness of Link local Addresses need only to be verified between the pairs of communicating nodes, a central router and a peripheral host. In that example, 2 peripheral hosts connected to the same central router can not have the same Link Local Address because the Binding Cache Entries (BCEs) would collide at the central router which could not talk to both over the same interface. The WiND operation is appropriate for that DAD operation, but the one from ND is not, because peripheral hosts are not on the same broadcast domain. On
the other hand, Global and ULA DAD is validated at the Subnet Level, using a registrar hosted by the central router.

4.3. Subnets and Global Addresses

WiND extends IPv6 ND for Hub-and-Spoke (e.g., BLE) and Route-Over (e.g., RPL) Multi-Link Subnets (MLSNs).

In the Hub-and-Spoke case, each Hub-Spoke pair is a distinct IP Link, and a Subnet can be mapped on a collection of Links that are connected to the Hub. The Subnet prefix is associated to the Hub. Acting as 6LR, the Hub advertises the prefix as not-onlink to the spokes in RA messages Prefix Information Options (PIO). Acting as 6LNs, the Spokes autoconfigure addresses from that prefix and register them to the Hub with a corresponding lifetime. Acting as a 6LBR, the Hub maintains a binding table of all the registered IP addresses and rejects duplicate registrations, thus ensuring a DAD protection for a registered address even if the registering node is sleeping. Acting as 6LR, the Hub also maintains an NCE for the registered addresses and can deliver a packet to any of them for their respective lifetimes. It can be observed that this design builds a form of Layer-3 Infrastructure BSS.

A Route-Over MLSN is considered as a collection of Hub-and-Spoke where the Hubs form a connected dominating set of the member nodes of the Subnet, and IPv6 routing takes place between the Hubs within the Subnet. A single logical 6LBR is deployed to serve the whole mesh. The registration in [RFC8505] is abstract to the routing protocol and provides enough information to feed a routing protocol such as RPL as specified in [I-D.thubert-roll-unaware-leaves]. In a degraded mode, all the Hubs are connected to a same high speed backbone such as an Ethernet bridging domain where IPv6 ND is operated. In that case, it is possible to federate the Hub, Spoke and Backbone nodes as a single Subnet, operating IPv6 ND proxy operations [I-D.ietf-6lo-backbone-router] at the Hubs, acting as 6BBRs. It can be observed that this latter design builds a form of Layer-3 Infrastructure ESS.

5. WiND Applicability

WiND allows P2P, P2MP hub-and-spoke, MAC-level broadcast domain emulation such as mesh-under and Wi-Fi BSS, and Route-Over meshes.

There is an intersection where Link and Subnet are congruent and where both ND and WiND could apply. These includes P2P, the MAC emulation of a PHY broadcast domain, and the particular case of always on, fully overlapping physical radio broadcast domain. But even in those cases where both are possible, WiND is preferable vs.
ND because it reduces the need of broadcast (this is discussed in the introduction of [I-D.ietf-6lo-backbone-router]).

There are also numerous practical use cases in the wireless world where Links and Subnets are not P2P and not congruent:

- IEEE std 802.11 infrastructure BSS enables one subnet per AP, and emulates a broadcast domain at L2. Infra ESS extends that and recommends to use an IPv6 ND proxy [IEEEstd80211] to coexist with Ethernet connected nodes. WiND incorporates an ND proxy to serve that need and that was missing so far.

- BlueTooth is Hub-and-Spoke at the MAC layer. It would make little sense to configure a different subnet between the central and each individual peripheral node (e.g., sensor). Rather, [RFC7668] allocates a prefix to the central node acting as router (6LR), and each peripheral host (acting as a host (6LR) forms one or more address(es) from that same prefix and registers it.

- A typical Smartgrid networks puts together Route-Over MLSNs that comprise thousands of IPv6 nodes. The 6TiSCH architecture [I-D.ietf-6tisch-architecture] presents the Route-Over model over a [IEEEstd802154] Time-Slotted Channel-Hopping mesh, and generalizes it for multiple other applications. Each node in a Smartgrid network may have tens to a hundred others nodes in range. A key problem for the routing protocol is which other node(s) should this node peer with, because most of the possible peers do not provide added routing value. When both energy and bandwidth are constrained, talking to them is a bad idea and most of the possible P2P links are not even used. Peerings that are actually used come and go with the dynamics of radio signal propagation. It results that allocating prefixes to all the possible P2P Links and maintain as many addresses in all nodes is not even considered.

5.1. Case of LPWANs

LPWANs are by nature so constrained that the addresses and Subnets are fully pre-configured and operate as P2P or Hub-and-Spoke. This saves the steps of neighbor Discovery and enables a very efficient stateful compression of the IPv6 header.

5.2. Case of Infrastructure BSS and ESS

In contrast to IPv4, IPv6 enables a node to form multiple addresses, some of them temporary to elusive, and with a particular attention paid to privacy. Addresses may be formed and deprecated asynchronously to the association. Even if the knowledge of IPv6
addresses used by a STA can be obtained by snooping protocols such as IPv6 ND and DHCPv6, or by observing data traffic sourced at the STA, such methods provide only an imperfect knowledge of the state of the STA at the AP. This may result in a loss of connectivity for some IPv6 addresses, in particular for addresses rarely used and in a situation of mobility. This may also result in undesirable remanent state in the AP when a STA ceases to use an IPv6 address. It results that snooping protocols is not a recommended technique and that it should only be used as last resort.

The recommended alternate is to use the IPv6 Registration method specified in p. By that method, the AP exposes its capability to proxy ND to the STA in Router Advertisement messages. In turn, the STA may request proxy ND services from the AP for one or more IPv6 addresses, using an Address Registration Option. The Registration state has a lifetime that limits unwanted state remanence in the network. The registration is optionally secured using [I-D.ietf-6lo-ap-nd] to prevent address theft and impersonation. The registration carries a sequence number, which enables a fast mobility without a loss of connectivity.

The ESS mode requires a proxy ND operation at the AP. The proxy ND operation must cover Duplicate Address Detection, Neighbor Unreachability Detection, Address Resolution and Address Mobility to transfer a role of ND proxy to the AP where a STA is associated following the mobility of the STA. The proxy ND specification associated to the address registration is [I-D.ietf-6lo-backbone-router]. With that specification, the AP participates to the protocol as a Backbone Router, typically operating as a bridging proxy though the routing proxy operation is also possible. As a bridging proxy, the proxy replies to NS lookups with the MAC address of the STA, and then bridges packets to the STA normally; as a routing proxy, it replies with its own MAC address and then routes to the STA at the IP layer. The routing proxy reduces the need to expose the MAC address of the STA on the wired side, for a better stability and scalability of the bridged fabric.

5.3. Case of Mesh Under Technologies

The Mesh-Under provides a broadcast domain emulation with reflexive and Transitive properties and defines a transit Link for IPv6 operations. It results that the model for IPv6 operation is similar to that of a BSS, with the root of the mesh operating an Access Point does in a BSS/ESS. While it is still possible to operate IPv6 ND, the inefficiencies of the flooding operation make the IPv6 ND operations even less desirable than in a BSS, and the use of WiND is highly recommended.
5.4. Case of DMC radios

IPv6 over DMC radios uses P2P Links that can be formed and maintained when a pair of DMC radios transmitters are in range from one another.

5.4.1. Using IPv6 ND only

DMC radios do not provide MAC level broadcast emulation. An example of that is IEEE Std. 802.11 OCB which uses IEEE Std. 802.11 MAC/PHYs but does not provide the BSS functions.

It is possible to form P2P IP Links between each individual pairs of nodes and operate IPv6 ND over those Links with Link Local addresses. DAD must be performed for all addresses on all P2P IP Links.

If special deployment care is taken so that the physical broadcast domains of a collection of the nodes fully overlap, then it is also possible to build an IP Subnet within that collection of nodes and operate IPv6 ND.

The model can be stretched beyond the scope of IPv6 ND if an external mechanism avoids duplicate addresses and if the deployment ensures the connectivity between peers. This can be achieved for instance in a Hub-and-Spoke deployment if the Hub is the only router in the Subnet and the Prefix is advertised as not onlink.

5.4.2. Using Wireless ND

Though this can be achieved with IPv6 ND, WiND is the recommended approach since it uses more unicast communications which are more reliable and less impacting for other users of the medium.

Router and Hosts respectively send a compressed RA/NA with a SLLAO at a regular period. The period can be indicated in a RA as in an RA-Interval Option [RFC6275]. If available, the message can be transported in a compressed form in a beacon, e.g., in OCB Basic Safety Messages (BSM) that are nominally sent every 100ms. An active beaoning mode is possible whereby the Host sends broadcast RS messages to which a router can answer with a unicast RA.

A router that has Internet connectivity and is willing to serve as an Internet Access may advertise itself as a default router [RFC4191] in its RA. The NA/RA is sent over an Unspecified Link where it does not conflict to anyone, so DAD is not necessary at that stage.

The receiver instantiates a Link where the sender’s address is not a duplicate. To achieve this, it forms an LLA that does not conflict with that of the sender and registers to the sender using [RFC8505].
If the sender sent an RA(PIO) the receiver can also autoconfigure an address from the advertised prefix and register it.

```

Figure 1: Initial Registration Flow

The lifetime in the registration should start with a small value (X=RMin, TBD), and exponentially grow with each reregistration to a larger value (X=Rmax, TBD). The IP Link is considered down when (X=NbBeacons, TBD) expected messages are not received in a row. It must be noted that the Link flapping does not affect the state of the registration and when a Link comes back up, the active -lifetime not elapsed- registrations are still usable. Packets should be held or destroyed when the Link is down.

P2P Links may be federated in Hub-and-Spoke and then in Route-Over MLSNs as described above. More details on the operation of WiND and RPL over the MLSN can be found in section 3.1, 3.2, 4.1 and 4.2.2 of [I-D.ietf-6tisch-architecture].
Figure 2: Initial Registration Flow over Multi-Link Subnet

An example Hub-and-Spoke is an OCB Road-Side Unit (RSU) that owns a prefix, provides Internet connectivity using that prefix to On-Board Units (OBUs) within its physical broadcast domain. An example of Route-Over MLSN is a collection of cars in a parking lot operating RPL to extend the connectivity provided by the RSU beyond its physical broadcast domain. Cars may then operate NEMO [RFC3963] for their own prefix using their address derived from the prefix of the RSU as CareOf Address.

6. IANA Considerations

This specification does not require IANA action.
7. Security Considerations

This specification refers to the security sections of IPv6 ND and 
WiND, respectively.

8. Acknowledgments

Many thanks to the participants of the 6lo WG where a lot of the work 
discussed here happened. Also ROLL, 6TiSCH, and 6LoWPAN.
