A Framework for Automating Service and Network Management with YANG
draft-wu-model-driven-management-virtualization-06

Abstract

Data models for service and network management provide a programmatic approach for representing (virtual) services or networks and deriving (1) configuration information that will be communicated to network and service components that are used to build and deliver the service and (2) state information that will be monitored and tracked. Indeed, data models can be used during various phases of the service and network management life cycle, such as service instantiation, service provisioning, optimization, monitoring, and diagnostic. Also, data models are instrumental in the automation of network management. They also provide closed-loop control for the sake of adaptive and deterministic service creation, delivery, and maintenance.

This document provides a framework that describes and discusses an architecture for service and network management automation that takes advantage of YANG modeling technologies. This framework is drawn from a network provider perspective irrespective of the origin of a data module; it can accommodate even modules that are developed outside the IETF.

The document aims to exemplify an approach that specifies the journey from technology-agnostic services to technology-specific actions.

1. Introduction

The service management system usually comprises service activation/provision and service operation. Current service delivery procedures, from the processing of customer’s requirements and order to service delivery and operation, typically assume the manipulation of data sequentially into multiple OSS/BSS applications that may be managed by different departments within the service provider’s organization (e.g., billing factory, design factory, network operation center, etc.). In addition, many of these applications have been developed in-house over the years and operating in a silo mode:

- The lack of standard data input/output (i.e., data model) also raises many challenges in system integration and often results in manual configuration tasks.

- Secondly, many current service fulfillment might not support real time streaming telemetry capability in high frequency and in high throughput on the current state of networking and therefore have slow response to the network changes.

Software Defined Networking (SDN) becomes crucial to address these challenges. SDN techniques [RFC7149] are meant to automate the overall service delivery procedures and typically rely upon (standard) data models that are used to not only reflect service
providers’savoir-faire but also to dynamically instantiate and enforce a set of (service-inferred) policies that best accommodate what has been (contractually) defined (and possibly negotiated) with the customer. [RFC7149] provides a first tentative to rationalize that service provider’s view on the SDN space by identifying concrete technical domains that need to be considered and for which solutions can be provided:

- Techniques for the dynamic discovery of topology, devices, and capabilities, along with relevant information and data models that are meant to precisely document such topology, devices, and their capabilities.
- Techniques for exposing network services [RFC8309] and their characteristics.
- Techniques used by service-requirement-derived dynamic resource allocation and policy enforcement schemes, so that networks can be programmed accordingly.
- Dynamic feedback mechanisms that are meant to assess how efficiently a given policy (or a set thereof) is enforced from a service fulfillment and assurance perspective.

Models are key for each of these technical items. Service and network management automation is an important step to improve the agility of network operations and infrastructures. Models are also important to ease integrating multi-vendor solutions.

YANG module developers have taken both top-down and bottom-up approaches to develop modules [RFC8199], and also to establish a mapping between network technology and customer requirements on the top or abstracting common construct from various network technologies on the bottom. At the time of writing this document (2019), there are many data models including configuration and service models that have been specified or are being specified by the IETF. They cover many of the networking protocols and techniques. However, how these models work together to configure a device, manage a set of devices involved in a service, or even provide a service is something that is not currently documented either within the IETF or other SDOs (e.g., MEF).

This document provides a framework that describes and discusses an architecture for service and network management automation that takes advantage of YANG modeling technologies and investigates how different layer YANG data models interact with each other (e.g., service mapping, model composing) in the context of service delivery and fulfillment.
This framework is drawn from a network provider perspective irrespective of the origin of a data module; it can accommodate even modules that are developed outside the IETF.

The document also identifies a list of use cases to exemplify the proposed approach, but it does not claim to be exhaustive.

It is not the intent of this document to provide an inventory of tools and mechanisms used in specific network and service management domains; such inventory can be found in documents such as [RFC7276].

2. Terminology

The following terms are defined in [RFC8309][RFC8199] and are not redefined here:

- Network Operator
- Customer
- Service
- Data Model
- Service Model
- Network Element Module

The document makes use of the following terms:

Network Resource Model: is used by a network operator to allocate a network resource (e.g., tunnel resource, topology resource) for the service or schedule the resource to meet the service requirements captured in a Service Model.

Device Model: Network Element YANG data module described in [RFC8199].

3. Architectural Concepts & Goals

3.1. Data Models: Layering and Representation

As described in [RFC8199], layering of modules allows for better reusability of lower-layer modules by higher-level modules while limiting duplication of features across layers.

The data modules developed by the IETF can be classified into service level, network level, and device level modules. Different service
level modules may rely on the same set of network level or device level modules.

Service level modules usually follow top down approach and are mostly customer-facing modules providing a common model construct for higher level network services (e.g., L3VPN), which can be further mapped to network technology-specific modules at lower layer (e.g., tunnel, routing, QoS, security). For example, the service level can be used to characterise the network service(s) to be ensured between service nodes (ingress/egress) such as the communication scope (pipe, hose, funnel, ...), the directionality, the traffic performance guarantees (one-way delay (OWD), one-way loss, ...), etc.

Network level modules mostly follow a bottom-up approach and are mainly network resource-facing modules and describe various aspects of a network infrastructure, including devices and their subsystems, and relevant protocols operating at the link and network layers across multiple devices (e.g., Network topology and traffic-engineering Tunnel modules).

Device (and function) level modules usually follow a bottom-up approach and are mostly technology-specific modules used to realize a service (e.g., BGP, NAT).

Each level maintains a view of the supported YANG modules provided by low-levels (see for example, Appendix A).

Figure 1 illustrates the overall layering model.
3.2. Automation of Service Delivery Procedures

To dynamically offer and deliver service offerings, Service level modules can be used by an operator. One or more monolithic Service modules can be used in the context of a composite service activation request (e.g., delivery of a caching infrastructure over a VPN). Such modules are used to feed a decision-making intelligence to adequately accommodate customer’s needs.
Also, such modules may be used jointly with services that require
dynamic invocation. An example is provided by the service modules
defined by the DOTS WG to dynamically trigger requests to handle DDoS
attacks [I-D.ietf-dots-signal-channel][I-D.ietf-dots-data-channel].

Network level modules can be derived from service level modules and
used to provision, monitor, instantiate the service, and provide
lifecycle management of network resources (e.g., expose network
resources to customers or operators to provide service fulfillment
and assurance and allow customers or operators to dynamically adjust
the network resources based on service requirements as described in
service level modules and the current network performance information
described in the telemetry modules).

3.3. Service Fullfillment Automation

To operate the service, Device level modules derived from Service
level modules or Network level modules can be used to provision each
involved network function/device with the proper configuration
information, and operate the network based on service requirements as
described in the Service level module(s).

In addition, the operational state including configuration that is in
effect together with statistics should be exposed to upper layers to
provide better network visibility (and assess to what extent the
derived low level modules are consistent with the upper level inputs).

Note that it is important to correlate telemetry data with
configuration data to be used for closed loops at the different
stages of service delivery, from resource allocation to service
operation, in particular.

3.4. YANG Modules Integration

To support top-down service delivery, YANG modules at different level
or at the same level need to be integrated together to enable
function, feature in the network device and get network setup. For
example, the service parameters captured in service level modules
need to be decomposed into a set of (configuration/notification)
parameters that may be specific to one or more technologies; these
technology-specific parameters are grouped together to define
technology-specific device level models or network level models.

In addition, these technology-specific device level models or network
level models can be further integrated with each other using schema
mount mechanism [RFC8528] to provision each involved network
function/device or each involved administrative domain to support
newly added module or features. A collection of device models integrated together can be loaded and validated during implementation time.

Policies provide a higher layer of abstraction. Policy models can be defined at service level, network level, or device level to provide policy-based management and telemetry automation, e.g., telemetry data can trigger a new policy that captures new network service requirements.

Performance measurement telemetry can be used to provide service assurance at service level or at the network level. Performance measurement telemetry model can tie with network level model or service level model to monitor network performance or service level agreement.

4. Architecture Overview

The architectural considerations described in Section 3 lead to the architecture described in this section and illustrated in Figure 2.
4.1. Service Lifecycle Management Procedure

Service lifecycle management includes end to end service lifecycle management at the service level and specific network lifecycle management at the network level. The end-to-end service lifecycle management is multi-domain or multi-layer service management while specific service lifecycle management is domain specific or layer specific service lifecycle management.

o Note: Clarify what is meant by "domain".
4.1.1.  Service Exposure

A service in the context of this document (sometimes called a Network Service) is some form of connectivity between customer sites and the Internet or between customer sites across the network operator’s network and across the Internet.

Service exposure is used to capture services offered to customers (ordering and order handling). One typical example is that a customer can use a L3SM service model to request L3VPN service by providing the abstract technical characterization of the intended service between customer sites.

Service model catalogs can be created along to expose the various services and the information needed to invoke/order a given service.

4.1.2.  Service Creation/Modification

A customer is (usually) unaware of the technology that the network operator has available to deliver the service, so the customer does not make requests specific to the underlying technology but is limited to making requests specific to the service that is to be delivered. This service request can be issued using the service model.

The service orchestrator/management system maps such service request to its view. This view can be described as a network model and this mapping may include a choice of which networks and technologies to use depending on which service features have been requested.

In addition, a customer may require to change underlying network infrastructure to adapt to new customer’s needs and service requirements. This service modification can be issued in the same service model used by the service request.

4.1.3.  Service Optimization

Service optimization is a technique that gets the configuration of the network updated due to network change, incident mitigation, or new service requirements. One typical example is once the tunnel or the VPN is setup, Performance monitoring information or telemetry information per tunnel or per VPN can be collected and fed into the management system, if the network performance doesn’t meet the service requirements, the management system can create new VPN policies capturing network service requirements and populate them into the network.
Both network performance information and policies can be modelled using YANG. With Policy-based management, self-configuration and self-optimization behavior can be specified and implemented.

4.1.4. Service Diagnosis

Operations, Administration, and Maintenance (OAM) are important networking functions for service diagnosis that allow operators to:

- monitor network communications (i.e., reachability verification and Continuity Check)
- troubleshoot failures (i.e., fault verification and localization)
- monitor service-level agreements and performance (i.e., performance management)

When the network is down, service diagnosis should be in place to pinpoint the problem and provide recommendation (or instructions) for the network recovery.

The service diagnosis information can be modelled as technology-independent RPC operations for OAM protocols and technology-independent abstraction of key OAM constructs for OAM protocols [RFC8531][RFC8533]. These models can provide consistent configuration, reporting, and presentation for the OAM mechanisms used to manage the network.

4.1.5. Service Decommission

Service decommission allow the customer to stop the service and remove the service from active status and release the network resource that is allocated to the service. Customer can also use the service model to withdraw the subscription to a service.

4.2. Service Fullfillment Management Procedure

4.2.1. Intended Configuration Provision

Intended configuration at the device level is derived from network model at the network level or service model at the service level and represents the configuration that the system attempts to apply. Take L3SM service model as an example, to deliver a L3VPN service, we need to map L3VPN service view defined in Service model into detailed intended configuration view defined by specific configuration models for network elements, configuration information includes:

- VRF definition, including VPN Policy expression
4.2.2. Configuration Validation

Configuration validation is used to validate intended configuration and ensure the configuration take effect. For example, a customer creates an interface "et-0/0/0" but the interface does not physically exist at this point, then configuration data appears in the <intended> status but does not appear in <operational> datastore.

4.2.3. Operational State Telemetry

<operational> datastore holds the complete operational state of the device including learned, system, default configuration and system state. <operational> datastore can be used as telemetry data source and allows the client subscribe to updates of a YANG datastore.

Based on criteria negotiated as part of a subscription, updates will be pushed to targeted recipients using YANG push mechanism [RFC8641].

4.2.4. Fault Diagnostic

Technology-dependent nodes and remote procedure call (RPC) commands are defined in technology-specific YANG modules which use and extend the base model described in Section 4.1.4.

These RPC commands received in the technology dependent node can be used to trigger technology specific OAM message exchange for fault verification and fault isolation.
4.3. Multi-layer/Multi-domain Service Mapping

Multi-layer/Multi-domain Service Mapping allow you map end to end abstract view of the service segmented at different layer or different administrative domain into domain specific view. One example is to map service parameters in L3VPN service model into configuration parameters such as RD, RT, and VRF in L3VPN network model. Another example is to map service parameters in L3VPN service model into TE tunnel parameter (e.g., Tunnel ID) in TE model and VN parameters (e.g., AP list, VN member) in TEAS VN model [I-D.ietf-teas-actn-vn-yang].

4.4. Service Decomposing

Service Decomposing allows to decompose service model at the service level or network model at the network level into a set of device/function models at the device level. These device models may be tied to specific device type or classified into a collection of related YANG modules based on service type and feature offered and load at the implementation time before configuration is loaded and validated.

5. YANG Data Model Integration Examples

5.1. L3VPN Service Delivery
In reference to Figure 3, the following steps are performed to deliver the L3VPN service within the network management automation architecture defined in this document:

1. Customer Requests to create two sites based on L3SM Service model with each having one network access connectivity:

   Site A: Network-Access A, Bandwidth=20M, for class "foo", guaranteed-bw-percent = 10, One-Way-Delay=70 msec

   Site B: Network-Access B, Bandwidth=30M, for class "foo1", guaranteed-bw-percent = 15, One-Way-Delay=60 msec

2. The Orchestrator extracts the service parameters from the L3SM model. Then, it uses them as input to translate them into an orchestrated configuration of network elements (e.g., RD, RT, VRF, etc.) that is part of the L3NM network model.

Figure 3: L3VPN Service Delivery Example
3. The Controller takes orchestrated configuration parameters in the L3NM network model and translates them into orchestrated configuration of network elements that is part of BGP model, QoS model, Network Instance model, IP management model, interface model, etc.

5.2. VN Lifecycle Management Example

![Diagram showing VN lifecycle management example]

In reference to Figure 4, the following steps are performed to deliver the VN service within the network management automation architecture defined in this document:

1. Customer requests to create ‘VN’ based on Access point, association between VN and Access point, VN member defined in the VN YANG module.

2. The orchestrator creates the single abstract node topology based on the information captured in an VN YANG module.

3. The Customer exchanges connectivity-matrix on abstract node and explicit path using TE topology model with the orchestrator. This information can be used to instantiate VN and setup tunnels between source and destination endpoints.
4. The telemetry which augments the TEAS VN model and corresponding TE Tunnel model can be used to notify all the parameter changes and network performance change related to VN topology or Tunnel [I-D.ietf-teas-actn-pm-telemetry-autonomics]. This information can be further used as input to ECA engine in the orchestrator and generate ECA policy model to optimize the network.

6. Security Considerations

Security considerations specific to each of the technologies and protocols listed in the document are discussed in the specification documents of each of these techniques.

(Potential) security considerations specific to this document are listed below:

- Create forwarding loops by mis-configuring the underlying network.
- Leak sensitive information: special care should be considered when translating between the various layers introduced in the document.
- ...
between the various layers introduced in the document.
- ...
tbc

7. IANA Considerations

There are no IANA requests or assignments included in this document.

Appendix A. Layered YANG Modules Example Overview

A.1. Service Models: Definition and Samples

As described in [RFC8309], the service is "some form of connectivity between customer sites and the Internet and/or between customer sites across the network operator's network and across the Internet". More concretely, an IP connectivity service can be defined as the IP transfer capability characterized by a (Source Nets, Destination Nets, Guarantees, Scope) tuple where "Source Nets" is a group of unicast IP addresses, "Destination Nets" is a group of IP unicast and/or multicast addresses, and "Guarantees" reflects the guarantees (expressed in terms of Quality Of Service (QoS), performance, and availability, for example) to properly forward traffic to the said "Destination" [RFC7297].

For example:

- L3SM model [RFC8299] defines the L3VPN service ordered by a customer from a network operator.
- L2SM model [RFC8466] defines the L2VPN service ordered by a customer from a network operator.
- VN model [I-D.ietf-teas-actn-vn-yang] provides a YANG data model generally applicable to any mode of Virtual Network (VN) operation.

Figure 5: Sample Resource Facing Network Models

Topology YANG module Examples:

- Network Topology Models: [RFC8345] defines a base model for network topology and inventories. Network topology data include link resource, node resource, and terminate-point resources.

- TE Topology Models: [I.D-ietf-teas-yang-te-topo] defines a data model for representing and manipulating TE topologies. This module is extended from network topology model defined in [RFC8345] with TE topologies specifics. This model contains technology-agnostic TE Topology building blocks that can be augmented and used by other technology-specific TE Topology models.

- L3 Topology Models

[RFC8346] defines a data model for representing and manipulating L3 Topologies. This model is extended from the network topology model defined in [RFC8345] with L3 topologies specifics.
o L2 Topology Models

[I.D-ietf-i2rs-yang-l2-topology] defines a data model for representing and manipulating L2 Topologies. This model is extended from the network topology model defined in [RFC8345] with L2 topologies specifics.

Tunnel YANG module Examples:

o Tunnel identities [I-D.ietf-softwire-iftunnel] to ease manipulating extensions to specific tunnels.

o TE Tunnel Model

[I.D-ietf-teas-yang-te] defines a YANG module for the configuration and management of TE interfaces, tunnels and LSPs.

o SR TE Tunnel Model

[I.D-ietf-teas-yang-te] augments the TE generic and MPLS-TE model(s) and defines a YANG module for Segment Routing (SR) TE specific data.

o MPLS TE Model

[I.D-ietf-teas-yang-te] augments the TE generic and MPLS-TE model(s) and defines a YANG module for MPLS TE configurations, state, RPC and notifications.

o RSVP-TE MPLS Model

[I.D-ietf-teas-yang-rsvp-te] augments the RSVP-TE generic module with parameters to configure and manage signaling of MPLS RSVP-TE LSPs.

Other Network Models:

o Path Computation API Model

[I.D-ietf-teas-path-computation] YANG module for a stateless RPC which complements the stateful solution defined in [I.D-ietf-teas-yang-te].

o OAM Models (including Fault Management (FM) and Performance Monitoring)

[RFC8532] defines a base YANG module for the management of OAM protocols that use Connectionless Communications. [RFC8533]
defines a retrieval method YANG module for connectionless OAM protocols.  [RFC8531] defines a base YANG module for connection oriented OAM protocols. These three models are intended to provide consistent reporting, configuration and representation for connection-less OAM and Connection oriented OAM separately.

Alarm monitoring is a fundamental part of monitoring the network. Raw alarms from devices do not always tell the status of the network services or necessarily point to the root cause.  [I.D-ietf-ccamp-alarm-module] defines a YANG module for alarm management.

- Generic Policy Model

  The Simplified Use of Policy Abstractions (SUPA) policy-based management framework [RFC8328] defines base YANG modules [I-D.ietf-supapolicy-data-model] to encode policy. These models point to device-, technology-, and service-specific YANG modules developed elsewhere. Policy rules within an operator’s environment can be used to express high-level, possibly network-wide, policies to a network management function (within a controller, an orchestrator, or a network element). The network management function can then control the configuration and/or monitoring of network elements and services. This document describes the SUPA basic framework, its elements, and interfaces.

A.3. Device Models: Definitions and Samples

  Network Element models (Figure 6) are used to describe how a service can be implemented by activating and tweaking a set of functions (enabled in one or multiple devices, or hosted in cloud infrastructures) that are involved in the service delivery. The following figure uses IETF defined models as an example.
A.3.1. Model Composition

- **Device Model**

[I.D-ietf-rtgwg-device-model] presents an approach for organizing YANG modules in a comprehensive logical structure that may be used to configure and operate network devices. The structure is itself
represented as an example YANG module, with all of the related component models logically organized in a way that is operationally intuitive, but this model is not expected to be implemented.

- Logical Network Element Model

[RFC8530] defines a logical network element module which can be used to manage the logical resource partitioning that may be present on a network device. Examples of common industry terms for logical resource partitioning are Logical Systems or Logical Routers.

- Network Instance Model

[RFC8529] defines a network instance module. This module can be used to manage the virtual resource partitioning that may be present on a network device. Examples of common industry terms for virtual resource partitioning are Virtual Routing and Forwarding (VRF) instances and Virtual Switch Instances (VSIs).

A.3.1.1. Schema Mount

Modularity and extensibility were among the leading design principles of the YANG data modeling language. As a result, the same YANG module can be combined with various sets of other modules and thus form a data model that is tailored to meet the requirements of a specific use case. [RFC8528] defines a mechanism, denoted schema mount, that allows for mounting one data model consisting of any number of YANG modules at a specified location of another (parent) schema.

That capability does not cover design time.

A.3.2. Device Models: Definitions and Samples

- BGP:  
  [I-D.ietf-idr-bgp-yang-model] defines a YANG module for configuring and managing BGP, including protocol, policy, and operational aspects based on data center, carrier and content provider operational requirements.

- MPLS:  
  [I-D.ietf-mpls-base-yang] defines a base model for MPLS which serves as a base framework for configuring and managing an MPLS switching subsystem. It is expected that other MPLS technology YANG modules (e.g. MPLS LSP Static, LDP or RSVP-TE models) will augment the MPLS base YANG module.
QoS:  
[I-D.asechoud-netmod-diffserv-model] describes a YANG module of Differentiated Services for configuration and operations.

ACL:  
Access Control List (ACL) is one of the basic elements used to configure device forwarding behavior. It is used in many networking technologies such as Policy Based Routing, Firewalls, etc.  
[RFC8519] describes a data model of Access Control List (ACL) basic building blocks.

NAT:  
For the sake of network automation and the need for programming Network Address Translation (NAT) function in particular, a data model for configuring and managing the NAT is essential.  
[RFC8512] defines a YANG module for the NAT function covering a variety of NAT flavors such as Network Address Translation from IPv4 to IPv4 (NAT44), Network Address and Protocol Translation from IPv6 Clients to IPv4 Servers (NAT64), customer-side translator (CLAT), Stateless IP/ICMP Translation (SIIT), Explicit Address Mappings (EAM) for SIIT, IPv6-to-IPv6 Network Prefix Translation (NPTv6), and Destination NAT.  
[RFC8513] specifies a YANG module for the DS-Lite AFTR.

Stateless Address Sharing:  
[I-D.ietf-softwire-yang] specifies a YANG module for A+P address sharing, including Lightweight 4over6, Mapping of Address and Port with Encapsulation (MAP-E), and Mapping of Address and Port using Translation (MAP-T) softwire mechanisms.

Multicast:  
[I-D.ietf-pim-yang] defines a YANG module that can be used to configure and manage Protocol Independent Multicast (PIM) devices.  
[I-D.ietf-pim-igmp-mld-yang] defines a YANG module that can be used to configure and manage Internet Group Management Protocol (IGMP) and Multicast Listener Discovery (MLD) devices.  
[I-D.ietf-pim-igmp-mld-snooping-yang] defines a YANG module that can be used to configure and manage Internet Group Management Protocol (IGMP) and Multicast Listener Discovery (MLD) Snooping devices.

EVPN:  
[I-D.ietf-bess-evpn-yang] defines a YANG module for Ethernet VPN services. The model is agnostic of the underlay. It apply to MPLS as well as to VxLAN encapsulation. The model is also agnostic of the services including E-LAN, E-LINE and E-TREE services. This document mainly focuses on EVPN and Ethernet-Segment instance framework.
L3VPN: [I-D.ietf-bess-l3vpn-yang] defines a YANG module that can be used to configure and manage BGP L3VPNs [RFC4364]. It contains VRF specific parameters as well as BGP specific parameters applicable for L3VPNs.

L2VPN: [I-D.ietf-bess-l2vpn-yang] defines a YANG module for MPLS based Layer 2 VPN services (L2VPN) [RFC4664] and includes switching between the local attachment circuits. The L2VPN model covers point-to-point VPWS and Multipoint VPLS services. These services use signaling of Pseudowires across MPLS networks using LDP [RFC8077][RFC4762] or BGP [RFC4761].

Routing Policy: [I-D.ietf-rtgwg-policy-model] defines a YANG module for configuring and managing routing policies in a vendor-neutral way and based on actual operational practice. The model provides a generic policy framework which can be augmented with protocol-specific policy configuration.

BFD: [I-D.ietf-bfd-yang] defines a YANG module that can be used to configure and manage Bidirectional Forwarding Detection (BFD) [RFC5880]. BFD is a network protocol which is used for liveness detection of arbitrary paths between systems.

SR/SRv6: [I-D.ietf-spring-sr-yang] a YANG module for segment routing configuration and operation. [I-D.raza-spring-srv6-yang] defines a YANG module for Segment Routing IPv6 (SRv6) base. The model serves as a base framework for configuring and managing an SRv6 subsystem and expected to be augmented by other SRv6 technology models accordingly.

Core Routing: [RFC8349] defines the core routing data model, which is intended as a basis for future data model development covering more-sophisticated routing systems. It is expected that other Routing technology YANG modules (e.g., VRRP, RIP, ISIS, OSPF models) will augment the Core Routing base YANG module.

PM:

[I.D-ietf-ippm-stamp-yang] defines the data model for implementations of Session-Sender and Session-Reflector for Simple Two-way Active Measurement Protocol (STAMP) mode using YANG.
[RFC8194] defines a data model for Large-Scale Measurement Platforms (LMAPs).
