Base Notifications for NMDA  
draft-wu-netconf-base-notification-nmda-01

Abstract

The Network Configuration Protocol (NETCONF) provides mechanisms to manipulate configuration datastores. NMDA introduces additional datastores for systems that support more advanced processing chains converting configuration to operational state. However, client applications are not able to be aware of common events pertaining to additional datastores, such as a data validation state change in NETCONF server, that may impact management applications. This document updates [RFC6470] to allow a NETCONF client to receive additional notifications for some common system events pertaining to the Network Management Datastore Architecture (NMDA) defined in [RFC8342].

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at https://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on December 21, 2018.

1.  Introduction

The Network Configuration Protocol (NETCONF) [RFC6470] provides mechanisms to manipulate configuration datastores. NMDA introduces additional datastores (e.g., <intended>, <operational>) for systems that support more advanced processing chains converting configuration to operational state. However, client applications are not able to be aware of common events pertaining to additional datastores, e.g., there are many background activities that happen during the time that configuration is committed to <running> to the time that the configuration is actually applied to <operational>. It is possible that some configuration could not be applied to <operational> due to either validation issues, or missing resource etc. There is a need for user to know the validation result of <intended> data-store and the reason why the configuration were not applied.

This document updates [RFC6470] to allows a NETCONF client to receive additional notifications for some common system events pertaining to the Network Management Datastore Architecture (NMDA) defined in [RFC8342]. These notification are not specific to any network management protocols such as NETCONF and RESTCONF.

The solution presented in this document is backwards compatible with [RFC6470].
1.1. Terminology

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [RFC2119] [RFC8174] when, and only when, they appear in all capitals, as shown here.

The following terms are defined in [RFC8342] and are not redefined here:

- operational state datastore
- running configuration datastore
- intended configuration datastore

2. Summary of Updates to RFC 6470

This document is intended to provide an extension of notifications initially defined within [RFC6470], with the development of NMDA architecture and data model. Key relationships between these two documents include:

- The existing notifications defined in [RFC6470] are remain unchanged, no additional information is added.
- A new event notification is defined in this document to overcome the shortcoming of [RFC6470] for supporting NMDA.

3. NETCONF Base Notifications YANG Model extension for NMDA

3.1. Overview

The YANG module in NETCONF Base Notifications [RFC6470] specifies the following 5 event notifications for the 'NETCONF' stream to notify a client application that the NETCONF server state has changed:

- netconf-config-change
- netconf-capability-change
- netconf-session-start
- netconf-session-end
- netconf-confirmed-commit
These event notifications used within the ‘NETCONF’ stream are accessible to clients via the subscription mechanism described in [RFC5277].

This document extends the YANG module defined in [RFC6470] to include NMDA specific extension which allows a NETCONF client to receive notifications for additional common system event as follows:

nmda-data-validate: Generated when a server with network management protocol support detects that a data validation event has occurred from the time that configuration is committed to <running> to the time that the configuration is actually applied to <operational> during management session. Indicates the event and the current state of the data validation. A server MAY report events for non-NETCONF management sessions (such as RESTCONF,gPRC), using the ‘session-id’ value of zero.

These notification messages are accessible to clients via either the subscription mechanism described in [RFC5277] or dynamic subscription mechanism and configured subscription mechanism described in [I-D.ietf-netconf-netconf-event-notifications].

The following are examples of a nmda-data-validation notification message:

```xml
<notification xmlns="urn:ietf:params:xml:ns:netconf:notification:1.0">
  <eventTime>2017-06-16T16:30:59.137045+09:00</eventTime>
    <username>admin</username>
    <session-id>0</session-id>
    <source-host>10.251.93.83</source-host>
    <validate-event>start</validate-event>
    <validate-result>partial-fail</validate-result>
    <validate-fail-target>
      <datastore>intended</datastore>
      <target>/ietf-interfaces:interfaces-state</target>
    </validate-fail-target>
    <validate-fail-target>
      <datastore>intended</datastore>
      <target>/ietf-system:system</target>
    </validate-fail-target>
  </nmda-data-validate>
</notification>
```
3.2. Definitions

This section presents the YANG module defined in this document. This module imports data types from the ‘ietf-netconf’ module defined in [RFC6241] and ‘ietf-inet-types’ module defined in [RFC6021].

```<CODE BEGINS> file "ietf-nmda-notifications@2018-04-01.yang"

} description "List for fail validate targets";

} <CODE ENDS>

4. Security Considerations

The YANG module defined in this memo is designed to be accessed via the NETCONF protocol [RFC6241]. The lowest NETCONF layer is the secure transport layer and the mandatory-to-implement secure transport is SSH, defined in [RFC6242].

Some of the readable data nodes in this YANG module may be considered sensitive or vulnerable in some network environments. It is thus important to control read access (e.g., via get, get-config, or notification) to these data nodes. These are the subtrees and data nodes and their sensitivity/vulnerability:

/nmda-data-validate/validate-event:

Indicates the specific validate-event state change that occurred. A value of 'complete' probably indicates that data validation procedure has completed.

5. IANA Considerations

This document registers one XML namespace URN in the 'IETF XML registry', following the format defined in [RFC3688]:

Registrant Contact: The IESG.

XML: N/A, the requested URI is an XML namespace.

This document registers one module name in the 'YANG Module Names' registry, defined in [RFC7950]:

   name: ietf-nmda-notifications
prefix: ncdn

RFC: xxxx
