SCTP NAT Traversal Considerations
draft-xie-behave-sctp-nat-cons-00.txt

Status of this Memo

This document is an Internet-Draft and is subject to all provisions of Section 3 of RFC 3667. By submitting this Internet-Draft, each author represents that any applicable patent or other IPR claims of which he or she is aware have been or will be disclosed, and any of which he or she become aware will be disclosed, in accordance with RFC 3668.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF), its areas, and its working groups. Note that other groups may also distribute working documents as Internet-Drafts.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

The list of current Internet-Drafts can be accessed at http://www.ietf.org/ietf/1id-abstracts.txt.

The list of Internet-Draft Shadow Directories can be accessed at http://www.ietf.org/shadow.html.

This Internet-Draft will expire on October 7, 2005.

Abstract

This document defines and classifies scenarios for the usage of SCTP
in networks with NATs and similar middleboxes.

2. Introduction

It is the job of Network Address Translators (NAT) [3] and middleboxes [6] that utilize a NAT function to manipulate address and port information in the IP and transport header. This poses a challenge for hosts that attempt to use certain end-to-end protocols [5]. This issue has drawn increasingly wide attention from the IP development and service community and much work has been done to ameliorate the situation for UDP, TCP and other protocols.

The same issue not only exists for SCTP [4], but also may become a more difficult issue when SCTP associations are multi-homed. This document defines and classifies scenarios dealing with SCTP and NAT traversal. In the following discussion, we will simply refer to NAT as a function, but note that many types of middleboxes employ NAT functions.

3. SCTP NAT Traversal Scenarios

3.1 Single Point Traversal

In this case, all packets in the SCTP association go through a single NAT, as shown below:

```
+---------+                           +---------+
|  SCTP   |          +-----+          |  SCTP   |
|end point|==========| NAT |==========|end point|
|    A    |          +-----+          |    B    |
+---------+                           +---------+
```

A variation of this case is shown below, i.e., multiple NATs in a single path:

```
+---------+                           +---------+
|  SCTP   |    +-----+     +-----+    |  SCTP   |
|end point|====| NAT |=::==| NAT |====|end point|
|    A    |    +-----+     +-----+    |    B    |
+---------+                           +---------+
```

The two SCTP endpoints in this case can be either single-homed or multi-homed. However, the important thing is that the NAT (or NATs)
in this case sees ALL the packets of the SCTP association.

In this single traverse point scenario, we must acknowledge that while one of the main benefits of SCTP multi-homing is redundant paths, the NAT function represents a single point of failure in the path of the SCTP multi-home association. However, the rest of the path may still benefit from path diversity provided by SCTP multi-homing.

3.2 Multi Point Traversal

This case involves multiple NATs and each NAT only sees some of the packets in the SCTP association. An example is shown below:

```
+-------+ /====|NAT A |====
| SCTP | /  +-------+ \ | SCTP |
| end point| / ... \ |end point|
| A \ ... / B |
+-------+ /====|NAT B |====/
```

This case does NOT apply to a singly-homed SCTP association (i.e., BOTH endpoints in the association use only one IP address). The advantage here is that the existence of multiple NAT traverse points can preserve the path diversity of a multi-homed association for the entire path. This in turn can improve the robustness of the communication.

To make this work, however, all the NATs involved must recognize the packets they see as belonging to the same SCTP association and perform address translation in a consistent way. It may be required that a pre-defined table of ports and addresses would be shared between the NAT’s. Other external management schemes that help multiple NAT’s coordinate a multi-homed SCTP association could be investigated.

4. Considerations for SCTP NAT Traversal

In any type of traverse, the NAT must understand the SCTP protocol. Since SCTP is relatively new (compared to UDP or TCP), some older existing NATs that are capable of handling UDP or TCP traverse will need to be enhanced for SCTP. In this section we discuss what considerations should be made for that NAT enhancement.

In a single-homed SCTP association, each endpoint uses only one IP address and the association will always go through a single NAT.
traverse point. It is important that the endpoints do not list the
IP-address again within the INIT or INIT-ACK chunks when setting up
the association. This makes sure that the NAT engine is not required
to change the INIT or INIT-ACK chunk when modifying the IP-addresses
of the packets containing the INIT and INIT-ACK chunks.

It is also important that the checksum of the whole SCTP packet has
to be recalculated if a part of the SCTP packet, for example port
numbers or IP-addresses listed in the INIT or INIT-ACK chunk, is
modified. It is not possible for the SCTP checksum to calculate the
difference of the checksum based only on the difference of the
packets like it is possible for the checksum used for TCP or UDP.

5. Security Considerations

See RFC XXXX on SCTP security considerations. See RFC XXXX on NAT
security considerations. See RFC XXXX for IAB comments on NAT.
