The Definitions of Managed Objects for
the Link Control Protocol of
the Point-to-Point Protocol

Status of this Memo

This RFC specifies an IAB standards track protocol for the Internet community, and requests discussion and suggestions for improvements. Please refer to the current edition of the "IAB Official Protocol Standards" for the standardization state and status of this protocol. Distribution of this memo is unlimited.

Abstract

This memo defines a portion of the Management Information Base (MIB) for use with network management protocols in TCP/IP-based internets. In particular, it describes managed objects used for managing the Link Control Protocol and Link Quality Monitoring on subnetwork interfaces that use the family of Point-to-Point Protocols [8, 9, 10, 11, & 12].

1. The Network Management Framework

The Internet-standard Network Management Framework consists of three components. They are:

STD 16/RFC 1155 which defines the SMI, the mechanisms used for describing and naming objects for the purpose of management. STD 16/RFC 1212 defines a more concise description mechanism, which is wholly consistent with the SMI.

STD 17/RFC 1213 which defines MIB-II, the core set of managed objects for the Internet suite of protocols.

STD 15/RFC 1157 which defines the SNMP, the protocol used for network access to managed objects.

The Framework permits new objects to be defined for the purpose of experimentation and evaluation.

2. Objects

Managed objects are accessed via a virtual information store, termed the Management Information Base or MIB. Objects in the MIB are defined using the subset of Abstract Syntax Notation One (ASN.1) [3] defined in the SMI. In particular, each object type is named by an OBJECT IDENTIFIER, an administratively assigned name. The object type together with an object instance serves to uniquely identify a specific instantiation of the object. For human convenience, we often use a textual string, termed the descriptor, to refer to the object type.

2.1. Format of Definitions

Section 4 contains the specification of all object types contained in this MIB module. The object types are defined using the conventions defined in the SMI, as amended by the extensions specified in [5, 6].

3. Overview

3.1. Object Selection Criteria

To be consistent with IAB directives and good engineering practice, an explicit attempt was made to keep this MIB as simple as possible. This was accomplished by applying the following criteria to objects proposed for inclusion:

(1) Require objects be essential for either fault or configuration management. In particular, objects for
which the sole purpose was to debug implementations were explicitly excluded from the MIB.

(2) Consider evidence of current use and/or utility.

(3) Limit the total number of objects.

(4) Exclude objects which are simply derivable from others in this or other MIBs.

3.2. Structure of the PPP

This section describes the basic model of PPP used in developing the PPP MIB. This information should be useful to the implementor in understanding some of the basic design decisions of the MIB.

The PPP is not one single protocol but a large family of protocols. Each of these is, in itself, a fairly complex protocol. The PPP protocols may be divided into three rough categories:

Control Protocols
The Control Protocols are used to control the operation of the PPP. The Control Protocols include the Link Control Protocol (LCP), the Password Authentication Protocol (PAP), the Link Quality Report (LQR), and the Challenge Handshake Authentication Protocol (CHAP).

Network Protocols
The Network Protocols are used to move the network traffic over the PPP interface. A Network Protocol encapsulates the datagrams of a specific higher-layer protocol that is using the PPP as a data link. Note that within the context of PPP, the term "Network Protocol" does not imply an OSI Layer-3 protocol; for instance, there is a Bridging network protocol.

Network Control Protocols (NCPs)
The NCPs are used to control the operation of the Network Protocols. Generally, each Network Protocol has its own Network Control Protocol; thus, the IP Network Protocol has its IP Control Protocol, the Bridging Network Protocol has its Bridging Network Control Protocol and so on.

This document specifies the objects used in managing one of these protocols, namely the Link Control Protocol and Link Quality Monitoring Protocol.
3.3. MIB Groups

Objects in this MIB are arranged into several MIB groups. Each group is organized as a set of related objects.

These groups are the basic unit of conformance: if the semantics of a group are applicable to an implementation then all objects in the group must be implemented.

The PPP MIB is organized into several MIB Groups, including, but not limited to, the following groups:

- The PPP Link Group
- The PPP LQR Group
- The PPP LQR Extensions Group
- The PPP IP Group
- The PPP Bridge Group
- The PPP Security Group

This document specifies the following groups:

The PPP Link Group

This group represents the lowest "level" of the PPP protocol.

This group contains two tables, one containing status information and the other configuration information. The configuration table is split off of the status so that it may be placed in a separate MIB View for security purposes.

Implementation of this group is mandatory for all PPP implementations.

The PPP LQR Group

This group provides the basic MIB variables that apply to the PPP LQR Protocol. This group provides MIB access to the information required for LQR processing. This group contains two tables, one containing status information and the other configuration information. The configuration table is split off of the status so that it may be placed in a separate MIB View for security purposes.

Implementation of the PPP LQR Group is mandatory for all PPP implementations that implement LQR.

The PPP LQR Extensions Group

The PPP LQR Extensions group contains the most recently received LQR packet, as well as the "save" fields that are "logically appended" [12] to received LQR packets. This is done in order to
facilitate external implementations of the Link Quality Monitoring policies.

It is not practical to examine the relevant MIB objects which are used to generate LQR packets since LQR policies may require synchronization of the values of all data used to determine Link Quality; i.e., the values of the relevant counters must all be taken at the same instant in time. Thus, by recording the last received LQR packet, a synchronized record of the relevant data is available.

As this information may not be efficiently maintained on all PPP implementations, implementation of this group is optional.

3.4. Relationship to Interface and Interface Extensions Groups

The PPP Mib is a medium-specific extension to the standard MIB-2 interface group [2] and to the Interface Extensions MIB [7]. This section discusses certain components of these groups when the interface is a PPP interface.

The PPP interface represents a single interface in the sense used in [2] and thus has a single entry in the ifTable.

Furthermore, the PPP interface may be operating over a lower layer hardware interface (such as an RS-232 port). It is important to capture the relationship between the PPP interface and the lower-layer interface over which it operates. This MIB presumes that the lower-layer interface has an ifEntry associated with it. The lower-layer ifEntry is identified via the pppLinkStatusPhysicalIndex object, which contains the value of ifIndex for the lower-layer ifEntry.

For example, suppose that you run PPP over a RS-232 port. This would use two entries in the ifTable. Let’s suppose that entry number 123 is for the PPP "interface" and entry number 987 is for the RS-232 port. So, ifSpecific.123 would contain the ppp OBJECT IDENTIFIER, pppLinkStatusPhysicalIndex.123 would contain 987, and ifSpecific.987 would contain the rs_232 OBJECT IDENTIFIER (or whatever it is).

All PPP packets are defined in [8] as being broadcast packets. Thus, the packets are counted as non-unicast packets in the ifTable (ifInNUcastPkts and ifOutNUCastPkts) and as broadcasts in the ifExtnsTable (ifExtnsBroadcastsReceivedOks and ifExtnsBroadcastsTransmittedOks).
ifSpecific
Contains the OBJECT IDENTIFIER ppp.

ifAdminStatus
Setting this object to up will inject an administrative open event into the LCP’s finite state machine. Setting this object to down will inject an administrative close event into the LCP’s finite state machine.

The use of the testing value is beyond the scope of this document.

ifOperStatus
Represents the state of the LCP Finite State Machine. If the Finite State Machine is in the Opened state then the value of ifOperStatus is up, otherwise the value of ifOperStatus is down.

The meaning of the testing value is beyond the scope of this document.

Per the SNMP Protocol Specification [13], the linkUp and linkDown traps apply to the PPP Protocol entity. When the LCP’s Finite State Machine attains the Opened state, a linkUp trap should be sent. When the Finite State Machine leaves the Opened state, a linkDown trap should be sent.

Some tests for the link are defined in this document. Execution of these tests does not place the link’s ifOperStatus in the testing state as these tests do not prevent normal data transmission from occurring over the link.

4. Definitions

PPP-LCP-MIB DEFINITIONS ::= BEGIN

IMPORTS
Counter
FROM RFC1155-SMI
ifIndex, transmission
FROM RFC1213-MIB
OBJECT-TYPE
FROM RFC-1212;

-- PPP MIB

ppp OBJECT IDENTIFIER ::= { transmission 23 }

pppLcp OBJECT IDENTIFIER ::= { ppp 1 }
-- The individual groups within the PPP-LCP-MIB

pppLink OBJECT IDENTIFIER ::= { pppLcp 1 }
pppLqr OBJECT IDENTIFIER ::= { pppLcp 2 }

-- 4.1. PPP Link Group

-- The PPP Link Group. Implementation of this group is mandatory for all PPP entities.

-- The following object reflect the values of the option parameters used in the PPP Link Control Protocol
-- pppLinkStatusLocalMRU
-- pppLinkStatusRemoteMRU
-- pppLinkStatusLocalToPeerACCMap
-- pppLinkStatusPeerToLocalACCMap
-- pppLinkStatusLocalToRemoteProtocolCompression
-- pppLinkStatusRemoteToLocalProtocolCompression
-- pppLinkStatusLocalToRemoteACCompression
-- pppLinkStatusRemoteToLocalACCompression
-- pppLinkStatusTransmitFcsSize
-- pppLinkStatusReceiveFcsSize

-- These values are not available until after the PPP Option negotiation has completed, which is indicated by the link reaching the open state (i.e., ifOperStatus is set to up).

-- Therefore, when ifOperStatus is not up the contents of these objects is undefined. The value returned when accessing the objects is an implementation dependent issue.

pppLinkStatusTable OBJECT-TYPE

"This object contains the most recently received LQR packet. The format of the packet is as described in the LQM Protocol specification. All fields of the packet, including the 'save' fields, are stored in this object.

The LQR packet is stored in network byte order. The LAP-B and PPP headers are not stored in this object; the first four octets of this variable contain the Magic-Number field, the second four octets contain the LastOutLQRs field and so on. The last four octets of this object contain the SaveInOctets field of the LQR packet."

REFERENCE
"Section 2.6, Packet Format, of RFC1333"
::= { pppLqrExtnsEntry 1 }

-- 4.4. PPP Tests

-- The extensions to the interface table in RFC1229 define a table through which the network manager can instruct the managed object to perform various tests of the interface. This is the ifExtnsTestTable.

-- The PPP MIB defines two such tests.

-- 4.4.1. PPP Echo Test

-- The PPP Echo Test is defined as

    pppEchoTest OBJECT IDENTIFIER ::= { pppTests 1 }

-- Invoking this test causes a PPP Echo Packet to be sent on the line. ifExtnsTestResult returns success(2) if the echo response came back properly. It returns failed(7) if the response did not properly return. The definition of "proper"
RFC 1471  PPP/LCP MIB  June 1993

-- in this context is left to the discretion of the implementor.

-- 4.4.2. PPP Discard Test

-- The PPP Discard Test is defined as

   pppDiscardTest OBJECT IDENTIFIER ::= { pppTests 2 }

-- Invoking this test causes a PPP Discard Packet to be sent on
-- the line. ifExtnsTestResult returns success(2) if the discard
-- packet was successfully transmitted and failed(7) if an error
-- was detected on transmission. The definition of "transmission
-- error" in this context is left to the discretion of the
-- implementor.

END

5. Acknowledgements

This document was produced by the PPP working group. In addition to
the working group, the author wishes to thank the following
individuals for their comments and contributions:

   Bill Simpson -- Daydreamer
   Glenn McGregor -- Merit
   Jesse Walker -- DEC
   Chris Gunner -- DEC

6. Security Considerations

The PPP MIB affords the network operator the ability to configure and
control the PPP links of a particular system. This represents a
security risk.

These risks are addressed in the following manners:

   (1) All variables which represent a significant security risk
       are placed in separate, optional, MIB Groups. As the MIB
       Group is the quantum of implementation within a MIB, the
       implementor of the MIB may elect not to implement these
       groups.

   (2) The implementor may choose to implement the variables
       which present a security risk so that they may not be
       written, i.e., the variables are READ-ONLY. This method
       still presents a security risk, and is not recommended,
       in that the variables, specifically the PPP
       Authentication Protocols’ variables, may be easily read.
(3) Using SNMPv2, the operator can place the variables into MIB views which are protected in that the parties which have access to those MIB views use authentication and privacy protocols, or the operator may elect to make these views not accessible to any party. In order to facilitate this placement, all security-related variables are placed in separate MIB Tables. This eases the identification of the necessary MIB View Subtree.
