Definitions of Managed Objects
for IEEE 802.3 Repeater Devices
using SMIV2

Status of this Memo

This document specifies an Internet standards track protocol for the Internet community, and requests discussion and suggestions for improvements. Please refer to the current edition of the "Internet Official Protocol Standards" (STD 1) for the standardization state and status of this protocol. Distribution of this memo is unlimited.

Abstract

This memo defines a portion of the Management Information Base (MIB) for use with network management protocols in the Internet community. In particular, it defines objects for managing IEEE 802.3 10 and 100 Mb/second baseband repeaters based on IEEE Std 802.3 Section 30, "10 & 100 Mb/s Management," October 26, 1995.

1. The SNMP Network Management Framework

   The SNMP Network Management Framework presently consists of three major components. They are:

   o    the SMI, described in RFC 1902 [6] - the mechanisms used for describing and naming objects for the purpose of management.

   o    the MIB-II, STD 17, RFC 1213 [5] - the core set of managed objects for the Internet suite of protocols.

   o    the protocol, STD 15, RFC 1157 [10] and/or RFC 1905 [9] - the protocol used for accessing managed information.

   Textual conventions are defined in RFC 1903 [7], and conformance statements are defined in RFC 1904 [8].

   The Framework permits new objects to be defined for the purpose of experimentation and evaluation.

1.1. Object Definitions

   Managed objects are accessed via a virtual information store, termed the Management Information Base or MIB. Objects in the MIB are defined using the subset of Abstract Syntax Notation one (ASN.1) defined in the SMI. In particular, each object type is named by an OBJECT IDENTIFIER, an administratively assigned name. The object type together with an object instance serves to uniquely identify a specific instantiation of the object. For human convenience, we often use a textual string, termed the descriptor, to refer to the object type.

2. Overview

2.1. Relationship to RFC 1516

   This MIB is intended as a superset of that defined by RFC 1516 [11], which will go to historic status. This MIB includes all of the objects contained in that MIB, plus several new ones which provide
for significant additional capabilities. Implementors are encouraged to support all applicable conformance groups in order to make the best use of the new functionality provided by this MIB. The new objects provide support for:

- multiple repeaters
- 100BASE-T management
- port TopN capability
- address search and topology mapping

Certain objects have been deprecated; in particular, those scalar objects used for managing a single repeater are now of minimal use since they are duplicated in the new multiple-repeater definitions. Additional objects have been deprecated based on implementation experience with RFC 1516.

2.2. Repeater Management

Instances of the object types defined in this memo represent attributes of an IEEE 802.3 (Ethernet-like) repeater, as defined by Section 9, "Repeater Unit for 10 Mb/s Baseband Networks" in the IEEE 802.3/ISO 8802-3 CSMA/CD standard [1], and Section 27, "Repeater for 100 Mb/s Baseband Networks" in the IEEE Standard 802.3u-1995 [2].

These Repeater MIB objects may be used to manage non-standard repeater-like devices, but defining objects to describe implementation-specific properties of non-standard repeater-like devices is outside the scope of this memo.

The definitions presented here are based on Section 30.4, "Layer Management for 10 and 100 Mb/s Baseband Repeaters" and Annex 30A, "GDMO Specificataions for 802.3 managed objects" of [3].

Implementors of these MIB objects should note that [3] explicitly describes when, where, and how various repeater attributes are measured. The IEEE document also describes the effects of repeater actions that may be invoked by manipulating instances of the MIB objects defined here.

The counters in this document are defined to be the same as those counters in [3], with the intention that the same instrumentation can be used to implement both the IEEE and IETF management standards.
2.3. Structure of the MIB

Objects in this MIB are arranged into packages, each of which contains a set of related objects within a broad functional category. Objects within a package are generally defined under the same OID subtree. These packages are intended for organizational convenience ONLY, and have no relation to the conformance groups defined later in the document.

2.3.1. Basic Definitions

The basic definitions include objects which are applicable to all repeaters: status, parameter and control objects for each repeater within the managed system, for the port groups within the system, and for the individual ports themselves.

2.3.2. Monitor Definitions

The monitor definitions include monitoring statistics for each repeater within the system and for individual ports.

2.3.3. Address Tracking Definitions

This collection includes objects for tracking the MAC addresses of the DTEs attached to the ports within the system and for mapping the topology of a network.

Note: These definitions are based on a technology which has been patented by Hewlett-Packard Company. HP has granted rights to this technology to implementors of this MIB. See [12] and [13] for details.

2.3.4. Top N Definitions

These objects may be used for tracking the ports with the most activity within the system or within particular repeaters.

2.4. Relationship to Other MIBs

2.4.1. Relationship to MIB-II

It is assumed that a repeater implementing this MIB will also implement (at least) the ‘system’ group defined in MIB-II [5].
2.4.1.1. Relationship to the ‘system’ group

In MIB-II, the ‘system’ group is defined as being mandatory for all systems such that each managed entity contains one instance of each object in the ‘system’ group. Thus, those objects apply to the entity even if the entity’s sole functionality is management of repeaters.

2.4.1.2. Relationship to the ‘interfaces’ group

In MIB-II, the ‘interfaces’ group is defined as being mandatory for all systems and contains information on an entity’s interfaces, where each interface is thought of as being attached to a ‘subnetwork’. (Note that this term is not to be confused with ‘subnet’ which refers to an addressing partitioning scheme used in the Internet suite of protocols.)

This Repeater MIB uses the notion of ports on a repeater. The concept of a MIB-II interface has NO specific relationship to a repeater’s port. Therefore, the ‘interfaces’ group applies only to the one (or more) network interfaces on which the entity managing the repeater sends and receives management protocol operations, and does not apply to the repeater’s ports.

This is consistent with the physical-layer nature of a repeater. A repeater is a bitwise store-and-forward device. It recognizes activity and bits, but does not process incoming data based on any packet-related information (such as checksum or addresses). A repeater has no MAC address, no MAC implementation, and does not pass packets up to higher-level protocol entities for processing.

(When a network management entity is observing a repeater, it may appear as though the repeater is passing packets to a higher-level protocol entity. However, this is only a means of implementing management, and this passing of management information is not part of the repeater functionality.)

    DESCRIPTION "Management information for 802.3 repeaters.
    The following references are used throughout
    this MIB module:

    [IEEE 802.3 Std]
    refers to IEEE 802.3/ISO 8802-3 Information
    processing systems - Local area networks -
    Part 3: Carrier sense multiple access with
collision detection (CSMA/CD) access method and physical layer specifications (1993).

[IEEE 802.3 Mgt]
refers to IEEE 802.3u-1995, ‘10 Mb/s & 100 Mb/s Management, Section 30,’ Supplement to ANSI/IEEE 802.3.

The following terms are used throughout this MIB module. For complete formal definitions, the IEEE 802.3 standards should be consulted wherever possible:

System - A managed entity compliant with this MIB, and incorporating at least one managed 802.3 repeater.

Chassis - An enclosure for one managed repeater, part of a managed repeater, or several managed repeaters. It typically contains an integral power supply and a variable number of available module slots.

Repeater-unit - The portion of the repeater set that is inboard of the physical media interfaces. The physical media interfaces (MAUs, AUIs) may be physically separated from the repeater-unit, or they may be integrated into the same physical package.

Trivial repeater-unit - An isolated port that can gather statistics.

Group - A recommended, but optional, entity defined by the IEEE 802.3 management standard, in order to support a modular numbering scheme. The classical example allows an implementor to represent field-replaceable units as groups of ports, with the port numbering matching the modular hardware implementation.

System interconnect segment - An internal segment allowing interconnection of ports belonging to different physical entities into the same logical manageable repeater. Examples of implementation might be backplane busses in modular hubs, or chaining cables in stacks of hubs.
Stack - A scalable system that may include managed repeaters, in which modularity is achieved by interconnecting a number of different chassis.

Module - A building block in a modular chassis. It typically maps into one 'slot'; however, the range of configurations may be very large, with several modules entering one slot, or one module covering several slots.

-- Old version of basic information at the repeater level.
--
-- In a system containing a single managed repeater, -- configuration, status, and control objects for the overall -- repeater.
-- The objects contained under the rptrRptrInfo subtree are
-- intended for backwards compatibility with implementations of
-- RFC 1516 [11]. In newer implementations (both single- and
-- multiple-repeater implementations) the rptrInfoTable should
-- be implemented. It is the preferred source of this information,
-- as it contains the values for all repeaters managed by the
-- agent. In all cases, the objects in the rptrRptrInfo subtree
-- are duplicates of the corresponding objects in the first entry
-- of the rptrInfoTable.

rptrGroupCapacity OBJECT-TYPE
SYNTAX Integer32 (1..2147483647)
MAX-ACCESS read-only
STATUS deprecated
DESCRIPTION "********* THIS OBJECT IS DEPRECATED **********
The rptrGroupCapacity is the number of groups
that can be contained within the repeater. Within
each managed repeater, the groups are uniquely
numbered in the range from 1 to rptrGroupCapacity.

Some groups may not be present in the repeater, in
which case the actual number of groups present
will be less than rptrGroupCapacity. The number
of groups present will never be greater than
rptrGroupCapacity.

Note: In practice, this will generally be the
number of field-replaceable units (i.e., modules,
cards, or boards) that can fit in the physical
repeater enclosure, and the group numbers will
correspond to numbers marked on the physical
enclosure."
REFERENCE
"[IEEE 802.3 Mgt], 30.4.1.1.3,
aRepeaterGroupCapacity."
::= { rptrRptrInfo 1 }

rptrOperStatus OBJECT-TYPE
SYNTAX INTEGER {
  other(1), -- undefined or unknown
  ok(2), -- no known failures
  rptrFailure(3), -- repeater-related failure
  groupFailure(4), -- group-related failure
  portFailure(5), -- port-related failure
  generalFailure(6) -- failure, unspecified type

**Thehipster** object indicates the operational state of the repeater. The **healthText** object may be consulted for more specific information about the state of the repeater’s health.

In the case of multiple kinds of failures (e.g., repeater failure and port failure), the value of this attribute shall reflect the highest priority failure in the following order, listed highest priority first:

1. **rptrFailure** (3)
2. **groupFailure** (4)
3. **portFailure** (5)
4. **generalFailure** (6).

```

**rptrReset** OBJECT-TYPE

SYNTAX INTEGER {

- noReset (1),
- reset (2)

- ... other values...

```
MAX-ACCESS read-write
STATUS        deprecated
DESCRIPTION   "********* THIS OBJECT IS DEPRECATED *********

Setting this object to reset(2) causes a transition to the START state of Fig 9-2 in section 9 [IEEE 802.3 Std] for a 10Mb/s repeater, and the START state of Fig 27-2 in section 27 of that standard for a 100Mb/s repeater.

Setting this object to noReset(1) has no effect. The agent will always return the value noReset(1) when this object is read.

After receiving a request to set this variable to reset(2), the agent is allowed to delay the reset for a short period. For example, the implementor may choose to delay the reset long enough to allow the SNMP response to be transmitted. In any event, the SNMP response must be transmitted.

This action does not reset the management counters defined in this document nor does it affect the portAdminStatus parameters. Included in this action is the execution of a disruptive Self-Test with the following characteristics: a) The nature of the tests is not specified. b) The test resets the repeater but without affecting management information about the repeater. c) The test does not inject packets onto any segment. d) Packets received during the test may or may not be transferred. e) The test does not interfere with management functions.

After performing this self-test, the agent will update the repeater health information (including rptrOperStatus and rptrHealthText), and send a rptrHealth trap."

REFERENCE
"[IEEE 802.3 Mgt], 30.4.1.2.1, acResetRepeater."
::= { rptrRptrInfo 4 }

rptrNonDisruptTest OBJECT-TYPE
SYNTAX INTEGER {
    noSelfTest(1),
    selfTest(2)
MAX-ACCESS read-write
STATUS deprecated
DESCRIPTION
"********* THIS OBJECT IS DEPRECATED *********

Setting this object to selfTest(2) causes the repeater to perform a agent-specific, non-
disruptive self-test that has the following characteristics: a) The nature of the tests is
not specified. b) The test does not change the state of the repeater or management information
about the repeater. c) The test does not inject packets onto any segment. d) The test does not
prevent the relay of any packets. e) The test does not interfere with management functions.

After performing this test, the agent will update the repeater health information (including
rpcoxOperStatus and rpcoxHealthText) and send a rpcoxHealth trap.

Note that this definition allows returning an 'okay' result after doing a trivial test.

Setting this object to noSelfTest(1) has no effect. The agent will always return the value
noSelfTest(1) when this object is read.

 ::=  { rptrPortEntry 2 }

rptrPortAdminStatus OBJECT-TYPE
SYNTAX      INTEGER {  
   enabled(1),  
   disabled(2)  
}
MAX-ACCESS  read-write
STATUS      current
DESCRIPTION
"Setting this object to disabled(2) disables the
port. A disabled port neither transmits nor
receives. Once disabled, a port must be
explicitly enabled to restore operation. A port
which is disabled when power is lost or when a
reset is exerted shall remain disabled when normal
operation resumes.

The admin status takes precedence over auto-
partition and functionally operates between the
auto-partition mechanism and the AUI/PMA.

Setting this object to enabled(1) enables the port
and exerts a BEGIN on the port’s auto-partition
state machine.

(In effect, when a port is disabled, the value of
rptrPortAutoPartitionState for that port is frozen
until the port is next enabled. When the port
becomes enabled, the rptrPortAutoPartitionState
becomes notAutoPartitioned(1), regardless of its
pre-disabling state.)"

REFERENCE
"[IEEE 802.3 Mgt], 30.4.3.1.2, aPortAdminState
and 30.4.3.2.1, acPortAdminControl."
::= { rptrPortEntry 3 }

rptrPortAutoPartitionState OBJECT-TYPE
SYNTAX      INTEGER {
            notAutoPartitioned(1),
            autoPartitioned(2)
}
MAX-ACCESS  read-only
STATUS      current
DESCRIPTION
"The autoPartitionState flag indicates whether the
port is currently partitioned by the repeater’s
auto-partition protection.

The conditions that cause port partitioning are
specified in partition state machine in Sections
9 and 27 of [IEEE 802.3 Std]. They are not
differentiated here."

REFERENCE
"[IEEE 802.3 Mgt], 30.4.3.1.3, aAutoPartitionState."
 ::= { rptrPortEntry 4 }

rptrPortOperStatus OBJECT-TYPE
SYNTAX      INTEGER {
    operational(1),
    notOperational(2),
    notPresent(3)
}
MAX-ACCESS  read-only
STATUS      current
DESCRIPTION
 "This object indicates the port’s operational status. The notPresent(3) status indicates the
port is physically removed (note this may or may not be possible depending on the type of port.)
The operational(1) status indicates that the port is enabled (see rptrPortAdminStatus) and working,
even though it might be auto-partitioned (see rptrPortAutoPartitionState).
If this object has the value operational(1) and rptrPortAdminStatus is set to disabled(2), it is
expected that this object’s value will soon change to notOperational(2)."
 ::= { rptrPortEntry 5 }

rptrPortRptrId OBJECT-TYPE
SYNTAX      Integer32 (0..2147483647)
MAX-ACCESS  read-only
STATUS      current
DESCRIPTION
 "This object identifies the repeater to which this port belongs. The repeater
identified by a particular value of this object is the same as that identified by the same
value of rptrInfoId. A value of zero indicates that this port currently is not
a member of any repeater."

rptrInfoReset OBJECT-TYPE
SYNTAX INTEGER {
   noReset(1),
   reset(2)
}
MAX-ACCESS read-write
STATUS current
DESCRIPTION
"Setting this object to reset(2) causes a
transition to the START state of Fig 9-2 in
section 9 [IEEE 802.3 Std] for a 10Mb/s repeater,
and to the START state of Fig 27-2 in section 27
of that standard for a 100Mb/s repeater.

Setting this object to noReset(1) has no effect.
The agent will always return the value noReset(1)
when this object is read.

After receiving a request to set this variable to
reset(2), the agent is allowed to delay the reset
for a short period. For example, the implementor may choose to delay the reset long enough to allow the SNMP response to be transmitted. In any event, the SNMP response must be transmitted.

This action does not reset the management counters defined in this document nor does it affect the portAdminStatus parameters. Included in this action is the execution of a disruptive Self-Test with the following characteristics: a) The nature of the tests is not specified. b) The test resets the repeater but without affecting management information about the repeater. c) The test does not inject packets onto any segment. d) Packets received during the test may or may not be transferred. e) The test does not interfere with management functions.

After performing this self-test, the agent will update the repeater health information (including rptrInfoOperStatus), and send a rptrInfoResetEvent notification.

-- the statistics object for the repeater-unit.
--
-- The objects contained under the rptrMonitorRptrInfo subtree are
-- intended for backwards compatibility with implementations of
-- RFC 1516 [11]. In newer implementations (both single- and
-- multiple-repeater implementations), the rptrMonitorTable will
-- be implemented. It is the preferred source of this information,
-- as it contains the values for all repeaters managed by the
-- agent. In all cases, the objects in the rptrMonitorRptrInfo
-- subtree are duplicates of the corresponding objects in the
-- first entry of the rptrMonitorTable.

rptrMonitorTransmitCollisions OBJECT-TYPE
SYNTAX Counter32
MAX-ACCESS read-only
STATUS deprecated
DESCRIPTION
"******* THIS OBJECT IS DEPRECATED **********

For a clause 9 (10Mb/s) repeater, this counter
is incremented every time the repeater state
machine enters the TRANSMIT COLLISION state
from any state other than ONE PORT LEFT
(Ref: Fig 9-2 [IEEE 802.3 Std]).

For a clause 27 repeater, this counter is
incremented every time the repeater core state
diagram enters the Jam state as a result of
Activity(ALL) > 1 (fig 27-2 [IEEE 802.3 Std]).
The approximate minimum time for rollover of this counter is 16 hours in a 10Mb/s repeater and 1.6 hours in a 100Mb/s repeater.

rptrMonitorPortReadableOctets OBJECT-TYPE
SYNTAX       Counter32
MAX-ACCESS   read-only
STATUS       current
DESCRIPTION
  "This object is the number of octets contained in
valid frames that have been received on this port.
This counter is incremented by OctetCount for each
frame received on this port which has been
determined to be a readable frame (i.e., including
FCS octets but excluding framing bits and dribble
bits).

A discontinuity may occur in the value
when the value of object
rptrMonitorPortLastChange changes.

This statistic provides an indicator of the total
data transferred. The approximate minimum time
for rollover of this counter in a 10Mb/s repeater
is 58 minutes.

For ports receiving traffic at a maximum rate in
a 100Mb/s repeater, this counter can roll over
in less than 6 minutes. Since that amount of time
could be less than a management station’s poll cycle
time, in order to avoid a loss of information a
management station is advised to also poll the
rptrMonitorPortUpper32Octets object, or to use the
64-bit counter defined by
rptrMonitorPortHCReadableOctets instead of the
two 32-bit counters."

::= { rptrMonitorPortEntry 7 }

rptrMonitorPortShortEvents OBJECT-TYPE
SYNTAX Counter32
MAX-ACCESS read-only
STATUS current
DESCRIPTION
"This counter is incremented by one for each CarrierEvent on this port with ActivityDuration less than ShortEventMaxTime. ShortEventMaxTime is greater than 74 bit times and less than 82 bit times. ShortEventMaxTime has tolerances included to provide for circuit losses between a conformance test point at the AUI and the measurement point within the state machine.

Notes:

ShortEvents may indicate externally generated noise hits which will cause the repeater to transmit Runts to its other ports, or propagate a collision (which may be late) back to the transmitting DTE and damaged frames to the rest of the network.

Implementors may wish to consider selecting the ShortEventMaxTime towards the lower end of the allowed tolerance range to accommodate bit losses suffered through physical channel devices not budgeted for within this standard.

The significance of this attribute is different in 10 and 100 Mb/s collision domains. Clause 9 repeaters perform fragment extension of short
events which would be counted as runts on the interconnect ports of other repeaters. Clause 27 repeaters do not perform fragment extension.

A discontinuity may occur in the value when the value of object rptrMonitorPortLastChange changes.

The approximate minimum time for rollover of this counter is 16 hours in a 10Mb/s repeater.

REFERENCE

"[IEEE 802.3 Mgt], 30.4.3.1.9, aShortEvents."

::= { rptrMonitorPortEntry 8 }

rptrMonitorPortRunts OBJECT-TYPE
SYNTAX Counter32
MAX-ACCESS read-only
STATUS current
DESCRIPTION "This counter is incremented by one for each CarrierEvent on this port that meets one of the following two conditions. Only one test need be made. a) The ActivityDuration is greater than ShortEventMaxTime and less than ValidPacketMinTime and the CollisionEvent signal is deasserted. b) The OctetCount is less than 64, the ActivityDuration is greater than ShortEventMaxTime and the CollisionEvent signal is deasserted. ValidPacketMinTime is greater than or equal to 552 bit times and less than 565 bit times.

An event whose length is greater than 74 bit times but less than 82 bit times shall increment either the shortEvents counter or the runts counter but not both. A CarrierEvent greater than or equal to 552 bit times but less than 565 bit times may or may not be counted as a runt.

ValidPacketMinTime has tolerances included to provide for circuit losses between a conformance test point at the AUI and the measurement point within the state machine.

Runts usually indicate collision fragments, a normal network event. In certain situations associated with large diameter networks a percentage of collision fragments may exceed ValidPacketMinTime.
A discontinuity may occur in the value when the value of object
rptrMonitorPortLastChange changes.

The approximate minimum time for rollover of this counter is 16 hours in a 10Mb/s repeater.

REFERENCE

::= { rptrMonitor100PortEntry 2 }

rptrMonitorPortUpper32Octets OBJECT-TYPE
SYNTAX      Counter32
MAX-ACCESS  read-only
STATUS      current
DESCRIPTION

"This object is the number of octets contained in
valid frames that have been received on this port,
modulo 2**32. That is, it contains the upper 32
bits of a 64-bit octets counter, of which the
lower 32 bits are contained in the
rptrMonitorPortReadableOctets object.

This two-counter mechanism is provided for those
network management protocols that do not support
64-bit counters (e.g. SNMP V1) and are used to
manage a repeater type of 100Mb/s.

Conformance clauses for this MIB are defined such
that implementation of this object is not required
in a system which does not support 100Mb/s.
However, systems with mixed 10 and 100Mb/s ports
may implement this object across all ports,
including 10Mb/s. If this object is implemented,
it must be according to the definition in the first
paragraph of this description; that is, the value
of this object MUST be a valid count.

A discontinuity may occur in the value
when the value of object
rptrMonitorPortLastChange changes."

::= { rptrMon100Entry 2 }
rfptrAddrSearchTable OBJECT-TYPE
SYNTAX SEQUENCE OF RptrAddrSearchEntry
MAX-ACCESS not-accessible
STATUS current
DESCRIPTION "This table contains one entry per repeater in the
system. It defines objects which allow a network
management application to instruct an agent to watch
for a given MAC address and report which port it
was seen on. Only one address search can be in
progress on each repeater at any one time. Before
starting an address search, a management application
should obtain ‘ownership’ of the entry in
rfptrAddrSearchTable for the repeater that is to
perform the search. This is accomplished with the
rfptrAddrSearchLock and rfptrAddrSearchStatus as
follows:

try_again:
  get(rptrAddrSearchLock, rptrAddrSearchStatus)
  while (rptrAddrSearchStatus != notInUse)
  {
    /* Loop waiting for objects to be available*/
    short delay
get(rptrAddrSearchLock, rptrAddrSearchStatus)
  }

  /* Try to claim map objects */
  lock_value = rptrAddrSearchLock
  if ( set(rptrAddrSearchLock = lock_value,
            rptrAddrSearchStatus = inUse,
            rptrAddrSearchOwner = 'my-IP-address)
      == FAILURE)
    /* Another manager got the lock */
goto try again

  /* I have the lock */
  set (rptrAddrSearchAddress = <search target>)

wait for rptrAddrSearchState to change from none

if (rptrAddrSearchState == single)
  get (rptrAddrSearchGroup, rptrAddrSearchPort)
/* release the lock, making sure not to overwrite anyone else’s lock */
set (rptrAddrSearchLock = lock_value+1,
    rptrAddrSearchStatus = notInUse,
    rptrAddrSearchOwner = '')

A management station first retrieves the values of the appropriate instances of the rptrAddrSearchLock and rptrAddrSearchStatus objects, periodically repeating the retrieval if necessary, until the value of rptrAddrSearchStatus is ‘notInUse’. The management station then tries to set the same instance of the rptrAddrSearchLock object to the value it just retrieved, the same instance of the rptrAddrSearchStatus object to ‘inUse’, and the corresponding instance of rptrAddrSearchOwner to a value indicating itself. If the set operation succeeds, then the management station has obtained ownership of the rptrAddrSearchEntry, and the value of rptrAddrSearchLock is incremented by the agent (as per the semantics of TestAndIncr). Failure of the set operation indicates that some other manager has obtained ownership of the rptrAddrSearchEntry.

Once ownership is obtained, the management station can proceed with the search operation. Note that the agent will reset rptrAddrSearchStatus to ‘notInUse’ if it has been in the ‘inUse’ state for an abnormally long period of time, to prevent a misbehaving manager from permanently locking the entry. It is suggested that this timeout period be between one and five minutes.

When the management station has completed its search operation, it should free the entry by setting the instance of the rptrAddrSearchLock object to the previous value + 1, the instance of the rptrAddrSearchStatus to ‘notInUse’, and the instance of rptrAddrSearchOwner to a zero length string. This is done to prevent overwriting another station’s lock."

"The monitored variable, which the rptrTopNPortRate variable is based upon.

The value of this object may not be modified if the associated rptrTopNPortRowStatus object has a value of active(1)."
::= { rptrTopNPortControlEntry 3 }

rptrTopNPortTimeRemaining OBJECT-TYPE
SYNTAX Integer32 (0..2147483647)
MAX-ACCESS read-create
STATUS current
DESCRIPTION
"The number of seconds left in the report currently being collected. When this object is modified by the management station, a new collection is started, possibly aborting a currently running report. The new value is used as the requested duration of this report, which is loaded into the associated rptrTopNPortDuration object.

When this object is set to a non-zero value, any associated rptrTopNPortEntries shall be made inaccessible by the agent. While the value of this object is non-zero, it decrements by one per second until it reaches zero. During this time, all associated rptrTopNPortEntries shall remain inaccessible. At the time that this object decrements to zero, the report is made accessible in the rptrTopNPortTable. Thus, the rptrTopNPort table needs to be created only at the end of the collection interval.

If the value of this object is set to zero while the associated report is running, the running report is aborted and no associated rptrTopNPortEntries are created."

DEFVAL { 0 }
::= { rptrTopNPortControlEntry 4 }

rptrTopNPortDuration OBJECT-TYPE
SYNTAX Integer32 (0..2147483647)
MAX-ACCESS read-only
STATUS current
DESCRIPTION
"The number of seconds that this report has collected during the last sampling interval, or if this report is currently being collected, the number of seconds that this report is being collected during this sampling interval.

When the associated rptrTopNPortTimeRemaining object is set, this object shall be set by the agent to the same value and shall not be modified until the next time the rptrTopNPortTimeRemaining is set.

This value shall be zero if no reports have been requested for this rptrTopNPortControlEntry."
::= { rptrTopNPortControlEntry 5 }  

rptrTopNPortRequestedSize OBJECT-TYPE
SYNTAX Integer32
MAX-ACCESS read-create
STATUS current
DESCRIPTION
"The maximum number of repeater ports requested for the Top N Table.

When this object is created or modified, the agent should set rptrTopNPortGrantedSize as close to this object as is possible for the particular implementation and available resources."
DEFVAL { 10 }
::= { rptrTopNPortControlEntry 6 }

END
4. Topology Mapping

The network mapping algorithm presented below takes information available from network devices such as repeaters, bridges, and switches, and creates a representation of the physical topology of the network.

Networking devices connect to the network via one or more ports. Through these ports, the device is capable of hearing network packets sent by other devices. By looking the source address in the packet, and identifying which port the packet was heard on, the device can provide information to a Network Management System about the location of an address in the network, relative to that device. For devices such as bridges and switches, the association of address to port can be retrieved via the forwarding data base part of the Bridge MIB. For repeaters, the rptrAddrSearchTable may be used to perform the association.

Given this information, it would be possible for the NMS to create a topology of the network which represents the physical relationships of the devices in the networks. The following is an example of how this might be done:

Assume the network:

```
    ===============
    |       |       |
    |       |       |
    d1     d4     d7
    / \     /     |
    /   \   /     |
    d2   d3 d5   |
    |     |     |
    |     |     |
    d6
```

The discovery process would first determine the existence of the network devices and nodes in the network. In the above example, the network devices discovered would be:

```
d1,d2,d3,d4,d5,d6,d7
```

From this list of discovered devices, select (arbitrarily or via some heuristic) a device as the starting point. From that device, determine where all other devices are located in the network with respect to the selected device.
For example, if d1 is the selected device, the network in relation to d1 would look like:

```
  d1
 / | \   
/  |  \   
 d2 d3 d4,d5,d6,d7
```

So d1 sees d2 on one port, d3 on another port, and d4, d5, and d6 on the third port. In other words, using the rptrAddrSearchTable (if d1 is a repeater) or the Forwarding Database (if it is a bridge or a switch), d1 has located d2 on one port, d1 has located d3 on another port, and finally, d1 has located d4, d5, d6, and d7 on yet another port.

After the first step of the algorithm is accomplished, the next and final step is a recursive one. Go to each of these temporary 'segments' (e.g., the segment connecting d1 and d2, or the segment connecting d1 and d3, or the segment connecting d1, d4, d5, d6, and d7) and determine which of these devices really belongs in that segment.

As new segments are created due to this process, the recursive algorithm visits them, and performs the exact same process.

In the example, the segments connecting d1 and d2, and connecting d1 and d3, require no further scrutiny, since there are only two nodes in those segments. However, the segment connecting d1, d4, d5, d6, and d7 may prove to be one or more segments, so we will investigate it.

The purpose of this step is to determine which devices are really connected to this segment, and which are actually connected downstream. This is done by giving each of the child devices in the segment (d4, d5, d6, and d7) a chance to eliminate each of the others from the segment.

A device eliminates another device by showing that it hears the parent device (in this case, d1) on one port, and the other device on another port (different from the port on which it heard the parent). If this is true, then it must mean that that device is _between_ the parent device and the device which is being eliminated.
In the example, we can see that device d4 can eliminate both d5 and d6, but nobody can eliminate d4 and d7, because everybody hears them on the same port that they hear the parent device (d1). So the resulting topology looks like:

```
  d1
 / | \    
/  |  \   
d2  d3  d4,d7
   |     
   d5,d6
```

Next the algorithm visits the next segment, which is the one connecting d4, d5, and d6. Using the process stated above, d5 can eliminate d6, since it hears d4 on a different port from where it hears d6. Finally, the topology looks like:

```
  d1
 / | \    
/  |  \   
d2  d3  d4,d7
   |     
   d5   
   |   
   d6
```

This is actually the topology shown at the beginning of the description.

With this information about how the network devices are connected, it is a relatively simple extension to then place nodes such as workstations and PCs in the network. This can be done by placing the node into a segment, then allowing the network devices to show that the node is really not part of that segment.

This elimination can be done because the devices know what port connects them to the segment on which the node is temporarily placed. If they actually hear the node on a different port than that which connects the device to the segment, then the node must be downstream, and so it is moved onto the downstream segment. Then that segment is evaluated, and so forth. Eventually, no device can show that the node is connected downstream, and so it must be attached to that segment.
For example, assume the network:

```
+-----+-----+-----+
|     |     |     |
| d1  | d4  | d7  |
+-----+-----+-----+
|     |     |     |
| d2  | d3  | d5  |
+-----+-----+-----+
|     |     |     |
| e1  |     |     |
+-----+-----+-----+
```

In this network, we are trying to place e1 where it belongs. We begin by placing it arbitrarily into a segment:

```
+-----+-----+-----+
|     |     |     |
| e1  | d1  | d4  | d7 |
+-----+-----+-----+
|     |     |     |
| d2  | d3  | d5  |
+-----+-----+-----+
|     |     |     |
|     |     |     |
| d6  |     |     |
```

In the above case, we would give d1, d4, and d7 a chance to show that e1 is not really on that segment. d4 and d7 hear e1 on the same port which connects them to that segment, so they cannot eliminate e1 from the segment. However, d1 will hear e1 on a different port, so we move e1 down onto the segment which is connected by that port. This yields the following:

```
+-----+-----+-----+
|     |     |     |
| d1  | d4  | d7  |
+-----+-----+-----+
|     |     |     |
| d2  | d3,e1| d5  |
+-----+-----+-----+
|     |     |     |
|     |     |     |
| d6  |     |     |
```
Now we give everyone in that segment (besides that parent device, d1) a chance to eliminate e1. Only d3 can try, and it succeeds, so we place e1 on segment which is connected by the port on which d3 heard e1. There is no segment there (yet), so we create one, and end up with the following:

```
+----------+  +----------+  +----------+
| d1       |  | d4       |  | d7       |
|          |  |          |  |          |
|          |  |          |  |          |
| \        |  | \        |  | \        |
| d2       |  | d3       |  | d5       |
|          |  |          |  |          |
|          |  |          |  |          |
| e1       |  | d6       |
```

which is the correct position.
