IESG Note

This document specifies an experimental MIB. Readers, implementers and users of this MIB should be aware that in the future the IETF may charter an IETF Working Group to develop a standards track MIB to address the same problem space that this MIB addresses. It is quite possible that an incompatible standards track MIB may result from that effort.

Abstract

This memo defines an experimental portion of the Management Information Base (MIB) for use with network management protocols in the Internet community. In particular, it defines a textual convention for doing Diffie-Helman key agreement key exchanges and a set of objects which extend the usmUserTable to permit the use of a DH key exchange in addition to the key change method described in [12]. In otherwords, this MIB adds the possibility of forward secrecy to the USM model. It also defines a set of objects that can be used to kick start security on an SNMPv3 agent when the out of band path is authenticated, but not necessarily private or confidential.

The KeyChange textual convention described in [12] permits secure key changes, but has the property that if a third-party has knowledge of the original key (e.g. if the agent was manufactured with a standard default key) and could capture all SNMP exchanges, the third-party would know the new key. The Diffie-Helman key change described here
limits knowledge of the new key to the agent and the manager making
the change. In otherwords, this process adds forward secrecy to the
key change process.

The recommendation in [12] is that the usmUserTable be populated out
of band - e.g. not via SNMP. If the number of agents to be
configured is small, this can be done via a console port and
manually. If the number of agents is large, as is the case for a
cable modem system, the manual approach doesn’t scale well. The
combination of the two mechanisms specified here - the DH key change
mechanism, and the DH key ignition mechanism - allows managable use
of SNMPv3 USM in a system of millions of devices.

This memo specifies a MIB module in a manner that is compliant to the
SNMP SMIv2[5][6][7]. The set of objects is consistent with the SNMP
framework and existing SNMP standards and is intended for use with
the SNMPv3 User Security Model MIB and other security related MIBs.

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT",
"SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this
document are to be interpreted as described in [16].

This memo is a private submission by the author, but is applicable to
the SNMPv3 working group within the Internet Engineering Task Force.
Comments are solicited and should be addressed to the the author.

1. The SNMP Management Framework

The SNMP Management Framework presently consists of five major components:

- An overall architecture, described in RFC 2271 [1].
- Mechanisms for describing and naming objects and events for the
  purpose of management. The first version of this Structure of
  Management Information (SMI) is called SMIV1 and described in STD

- Message protocols for transferring management information. The first version of the SNMP message protocol is called SNMPv1 and described in STD 15, RFC 1157 [8]. A second version of the SNMP message protocol, which is not an Internet standards track protocol, is called SNMPv2c and described in RFC 1901 [9] and RFC 1906 [10]. The third version of the message protocol is called SNMPv3 and described in RFC 1906 [10], RFC 2272 [11] and RFC 2274 [12].

- Protocol operations for accessing management information. The first set of protocol operations and associated PDU formats is described in STD 15, RFC 1157 [8]. A second set of protocol operations and associated PDU formats is described in RFC 1905 [13].

- A set of fundamental applications described in RFC 2273 [14] and the view-based access control mechanism described in RFC 2275 [15].

Managed objects are accessed via a virtual information store, termed the Management Information Base or MIB. Objects in the MIB are defined using the mechanisms defined in the SMI.

This memo specifies a MIB module that is compliant to the SMIv2. A MIB conforming to the SMIv1 can be produced through the appropriate translations. The resulting translated MIB must be semantically equivalent, except where objects or events are omitted because no translation is possible (use of Counter64). Some machine readable information in SMIv2 will be converted into textual descriptions in SMIv1 during the translation process. However, this loss of machine readable information is not considered to change the semantics of the MIB.

1.1. Structure of the MIB

This MIB is structured into three groups and a single textual convention:

- The DHKeyChange textual convention defines the process for changing a secret key value via a Diffie-Helman key exchange.

- The usmDHPublicObjects group contains a single object which describes the public Diffie-Helman parameters required by any instance of a DHKeyChange typed object.
The usmDHUserKeyTable augments and extends the usmUserTable defined in the SNMPv3 User-based Security Model MIB [12] by providing objects which permit the updating of the Authentication and Privacy keys for a row in this table through the use of a Diffie-Helman key exchange.

The usmDHKickstartTable provides a mechanism for a management station to be able to agree upon a set of authentication and confidentiality keys and their associated row in the usmUserTable.

2. Theory of Operation

2.1. Diffie-Helman Key Changes

Upon row creation (in the usmUserTable), or object change (either of the object in the usmDHUserKeyTable or its associated value in the usmUserTable), the agent generates a random number. From this random number, the agent uses the DH parameters and transforms to derive a DH public value which is then published to the associated MIB object. The management station reads one or more of the objects in the usmDHUserKeyTable to get the agent’s DH public values.

The management station generates a random number, derives a DH public value from that random number (as described in the DHKeyChange Textual Convention), and does an SNMP SET against the object in the usmDHUserKeyTable. The set consists of the concatenation of the agent’s derived DH public value and the manager’s derived DH public value (to ensure the DHKeyChange object hasn’t otherwise changed in the meantime).

Upon successful completion of the set, the underlying key (authentication or confidentiality) for the associated object in the usmUserTable is changed to a key derived from the DH shared secret. Both the agent and the management station are able to calculate this value based on their knowledge of their own random number and the other’s DH public number.

2.2. Diffie-Helman Key Ignition

[12] recommends that the usmUserTable be populated out of band, for example – manually. This works reasonably well if there are a small number of agents, or if all the agents are using the same key material, and if the device is physically accessible for that action. It does not scale very well to the case of possibly millions of devices located in thousands of locations in hundreds of markets in
multiple countries. In other words, it doesn’t work well with a cable modem system, and may not work all that well with other large-scale consumer broadband IP offerings.

The methods described in the objects under the usmDHKickstartGroup can be used to populate the usmUserTable in the circumstances where you may be able to provide at least limited integrity for the provisioning process, but you can’t guarantee confidentiality. In addition, as a side effect of using the DH exchange, the operational USM keys for each agent will differ from the operational USM keys for every other device in the system, ensuring that compromise of one device does not compromise the system as a whole.

The vendor who implements these objects is expected to provide one or more usmSecurityNames which map to a set of accesses defined in the VACM [15] tables. For example, the vendor may provide a ‘root’ user who has access to the entire device for read-write, and ‘operator’ user who has access to the network specific monitoring objects and can also reset the device, and a ‘customer’ user who has access to a subset of the monitoring objects which can be used to help the customer debug the device in conjunction with customer service questions.

To use, the system manager (the organization or individual who own the group of devices) generates one or more random numbers – R. The manager derives the DH Public Numbers R’ from these random numbers, associates the public numbers with a security name, and configures the agent with this association. The configuration would be done either manually (in the case of a small number of devices), or via some sort of distributed configuration file. The actual mechanism is outside the scope of this document. The agent in turn generates a random number for each name/number pair, and publishes the DH Public Number derived from its random number in the usmDHKickstartTable along with the manager’s public number and provided security name.

Once the agent is initialized, an SNMP Manager can read the contents of the usmDHKickstartTable using the security name of ‘dhKickstart’ with no authentication. The manager looks for one or more entries in this table where it knows the random number used to derive the usmDHKickstartMgrPublic number. Given the manager’s knowledge of the private random number, and the usmDHKickstartMyPublic number, the manager can calculate the DH shared secret. From that shared secret, it can derive the operational authentication and confidentiality keys for the usmUserTable row which has the matching security name. Given the keys and the security name, the manager can then use normal USM mechanisms to access the remainder of the agent’s MIB space.

STATUS current
DESCRIPTION
"Upon initialization, or upon creation of a row containing an
object of this type, and after any successful SET of this value, a
GET of this value returns 'y' where y = g^xa MOD p, and where g is
the base from usmDHParameters, p is the prime from
usmDHParameters, and xa is a new random integer selected by the
agent in the interval 2^(l-1) <= xa < 2^l < p-1. 'l' is the
optional privateValueLength from usmDHParameters in bits. If 'l'
is omitted, then xa (and xr below) is selected in the interval 0
<= xa < p-1. y is expressed as an OCTET STRING 'PV' of length 'k'
which satisfies

\[ y = \sum_{i=1}^{k} 2^{8(k-i)} \text{PV}'i \]

where PV1,...,PVk are the octets of PV from first to last, and
where PV1 <> 0.

A successful SET consists of the value 'y' expressed as an OCTET
STRING as above concatenated with the value 'z'(expressed as an
OCTET STRING in the same manner as y) where z = g^xr MOD p, where
g, p and l are as above, and where xr is a new random integer
selected by the manager in the interval 2^(l-1) <= xr < 2^l <
p-1. A SET to an object of this type will fail with the error
wrongValue if the current 'y' does not match the 'y' portion of
the value of the varbind for the object. (E.g. GET yout, SET
concat(yin, z), yout <> yin).

Note that the private values xa and xr are never transmitted from
manager to device or vice versa, only the values y and z.
Obviously, these values must be retained until a successful SET on
the associated object.

The shared secret 'sk' is calculated at the agent as sk = z^xa MOD
p, and at the manager as sk = y^xr MOD p.

Each object definition of this type MUST describe how to map from
the shared secret 'sk' to the operational key value used by the
protocols and operations related to the object. In general, if n
bits of key are required, the author suggests using the n
right-most bits of the shared secret as the operational key value."

usmDHKickstartMgrPublic OBJECT-TYPE
SYNTAX OCTET STRING
MAX-ACCESS read-only
STATUS current
DESCRIPTION

"The manager’s Diffie-Hellman public value for this row. Note
that this value is not set via the SNMP agent, but may be set via
some out of band method, such as the device’s configuration file."
The manager calculates this value in the same manner and using the same parameter set as the agent does. E.g. it selects a random number ‘r’, calculates y = g^r mod p and provides ‘y’ as the public number expressed as an OCTET STRING. See usmDHKickstartMyPublic for details.

When this object is set with a valid value during initialization, a row is created in the usmUserTable with the following values:

<table>
<thead>
<tr>
<th>usmUserEngineID</th>
<th>localEngineID</th>
</tr>
</thead>
<tbody>
<tr>
<td>usmUserName</td>
<td>[value of usmDHKickstartSecurityName]</td>
</tr>
<tr>
<td>usmUserSecurityName</td>
<td>[value of usmDHKickstartSecurityName]</td>
</tr>
<tr>
<td>usmUserCloneFrom</td>
<td>ZeroDotZero</td>
</tr>
<tr>
<td>usmUserAuthProtocol</td>
<td>usmHMACMD5AuthProtocol</td>
</tr>
<tr>
<td>usmUserAuthKeyChange</td>

<td>''</td>
</tr>
<tr>
<td>usmUserStorageType</td>
<td>permanent</td>
</tr>
<tr>
<td>usmUserStatus</td>
<td>active</td>
</tr>
</tbody>
</table>

A shared secret ‘sk’ is calculated at the agent as sk = mgrPublic^r mod p where r is the agents random number and p is the DH prime from the common parameters. The underlying privacy key for this row is derived from sk by applying the key derivation function PBKDF2 defined in PKCS#5v2.0 with a salt of 0xd1310ba6, and iterationCount of 500, a keyLength of 16 (for usmDESPrivProtocol), and a prf (pseudo random function) of ‘id-hmacWithSHA1’. The underlying authentication key for this row is derived from sk by applying the key derivation function PBKDF2 with a salt of 0x98dfb5ac, an iteration count of 500, a keyLength of 16 (for usmHMAC5AuthProtocol), and a prf of ‘id-hmacWithSHA1’. Note: The salts are the first two words in the ks0 [key schedule 0] of the BLOWFISH cipher from ‘Applied Cryptography’ by Bruce Schnier - they could be any relatively random string of bits.

The manager can use its knowledge of its own random number and the agent’s public value to kickstart its access to the agent in a secure manner. Note that the security of this approach is directly related to the strength of the authorization security of the out of band provisioning of the managers public value (e.g. the configuration file), but is not dependent at all on the strength of the confidentiality of the out of band provisioning data.”

5. Security Considerations

Objects in the usmDHUserKeyTable should be considered to have the same security sensitivity as the objects of the KeyChange type in usmUserTable and should be afforded the same level of protection. Specifically, the VACM should not grant more or less access to these objects than it grants to the usmUserTable KeyChange object.

The improper selection of parameters for use with Diffie-Hellman key changes may adversely affect the security of the agent. Please see the body of the MIB for specific recommendations or requirements on the selection of the DH parameters.
An unauthenticated DH exchange is subject to "man-in-the-middle" attacks. The use of the DH exchange in any specific environment should balance risk versus threat.

Good security from a DH exchange requires a good source of random numbers. If your application cannot provide a reasonable source of randomness, do not use a DH exchange. For more information, see "Randomness Recommendations for Security" [19].

6. Intellectual Property

The IETF takes no position regarding the validity or scope of any intellectual property or other rights that might be claimed to pertain to the implementation or use of the technology described in this document or the extent to which any license under such rights might or might not be available; neither does it represent that it has made any effort to identify any such rights. Information on the IETF’s procedures with respect to rights in standards-track and standards-related documentation can be found in BCP-11. Copies of claims of rights made available for publication and any assurances of licenses to be made available, or the result of an attempt made to obtain a general license or permission for the use of such proprietary rights by implementors or users of this specification can be obtained from the IETF Secretariat.

The IETF invites any interested party to bring to its attention any copyrights, patents or patent applications, or other proprietary rights which may cover technology that may be required to practice this standard. Please address the information to the IETF Executive Director.
