Abstract

The goal of this document is to produce a streamlined, fast, easily managed, and cryptographically sound protocol without requiring public key.

Motivation

The IPsec working group has defined a number of protocols which provide the ability to create and maintain cryptographically secure security associations at layer three (i.e., the IP layer). This effort has produced two distinct protocols:

1) a mechanism to encrypt and authenticate IP datagram payloads which assumes a shared secret between the sender and receiver

2) a mechanism for IPsec peers to perform mutual authentication and exchange keying material

The IPsec working group has defined a peer to peer authentication and keying mechanism, IKE (RFC 2409). One of the drawbacks of a peer to peer protocol is that each peer must know and implement a site’s security policy which in practice can be quite complex. In addition, the lack of a trusted third party requires the use of Diffie Hellman (DH) to establish a shared secret. DH, unfortunately, is computationally quite expensive and prone to denial of service attacks. IKE also relies on X.509 certificates to realize scalable authentication of peers. Digital signatures are also computationally expensive and certificate based trust models are difficult to deploy.
in practice. While IKE does allow for pre-shared symmetric keys, key
distribution is required between all peers -- an $O(n^2)$ problem --
which is problematic for large deployments.

Kerberos (RFC 1510) provides a mechanism for trusted third party
authentication for clients and servers. Clients authenticate to a
centralized server -- the Key Distribution Center -- which in turn
issues tickets that servers can decrypt thus proving that the client
is who it claims to be. One of the elements of a Kerberos ticket is
a session key which is generated by the KDC which may be used by the
client and server to share a secret. Kerberos also allows for both
symmetric key authentication, as well as certificate based public key
authentication (PKinit). Since the authentication phase of Kerberos
is performed by the KDC, there is no need to perform expensive DH or
X.509 certificate signatures/verification operations on servers.
While clients may authenticate using X.509 certificates, the
authentication phase can be amortized over the lifetime of the
credentials. This allows a single DH and certificate exchange to be
used to key security associations with many servers in a
computationally economic way. Kerberos also support clients with
symmetric keys but unlike IKE, the symmetric keys are stored in the
KDC making the number of keys an $O(n)$ problem rather than $O(n^2)$.
Kerberos also allows security policy to be managed in a more
centralized fashion, rather than expecting each potentially
untrustworthy peer to abide by stated security policies of an
organization.

The KINK working group takes these basic features of Kerberos and
uses them to its advantage to create a protocol which can establish
and maintain IPsec security associations (RFC 2401). It should be
noted that KINK is not a replacement for IKE. IKE has one property
which KINK cannot reproduce: the ability for two peers to mutually
authenticate and exchange keys without the need for an actively
participating third party. However, there are many situations where
a trusted third party which proxies authentication is viable, and in
fact desirable.

While Kerberos specifies a standard protocol between the client and
the KDC to get tickets, the actual ticket exchange between client and
server is application specific. KINK is intended to be an
alternative to requiring each application having its own method of
transporting and validating service tickets using a protocol which is
efficient and tailored to the specific needs of Kerberos and the
applications for which it provides keying and parameter negotiation.

Given the above, a new general keying protocol which leverages the
scalability of Kerberos is desirable. The working group’s first task
is to define this protocol and define an domain of interpretation for
IPsec to establish and maintain IPsec security associations. The protocol must be able to take full advantage of the features of RFC 2401 but in the context of a centralized keying authority.

Requirements

KINK must meet the following requirements at a minimum:

- The protocol must use the session keys found in Kerberos tickets as the basis of the keying material used for IPsec security association keys.

- The protocol must be able to integrate into security architecture of IPsec (RFC 2401).

- The protocol must be able to start up SA’s regardless of any client/server disposition in the keying protocol. In other words, either IPsec peer can be the initiator or responder, regardless of whether it’s a Kerberos ‘client’ (TGT-only) or Kerberos ‘server’ (has a keytab).

- The protocol must support Kerberos using either secret key, or public key (PKINIT) initial authentication.

- The protocol must support Kerberos User-to-User mode for cases in which the initiator cannot obtain an AP_REQ for the responder (i.e., the responder is a PKINIT client) or the responder cannot decrypt and AP_REQ from the initiator (i.e., the responder doesn’t have a Kerberos Keytab, just a TGT).

- The protocol must be able to allow a peer to authenticate and participate in many realms.

- The protocol must handle absolute time skew gracefully.

- The protocol must be able to create, modify, rekey, and delete security associations.

- The protocol must be capable of setting up both transport and tunnel modes of IPsec.

- The protocol must be capable of setting up both AH and ESP security associations.

- The protocol must be capable of negotiating cipher suites.

- The protocol must be capable of setting up IPsec flow selectors.
The protocol must be capable of rekeying without the assistance of the KDC if the Kerberos session ticket is still valid.

The protocol must make an effort to mitigate third party Denial of Service attacks (aka Zombies attacks).

The protocol must be able to be used for more than IPsec keying.

The protocol must support both IPv4 and IPv6.

Security Considerations

These requirements lay out input to define a protocol which allows the keying of IPsec security associations using Kerberos as the key distribution mechanism. As such, the security associations that will be created by the new protocol will inherit the union of IPsec and Kerberos’s existing security weaknesses. There is no requirement to address those weaknesses unless in combination they produce a new weakness which is not inherent in other keying protocols.

Acknowledgments

The original KINK Kabal was:

  Michael Thomas (Cisco)
  David McGrew (Cisco)
  Jan Vilhuber (Cisco)
  Jonathan Trostle (Cisco)
  Matt Hur (Cybersafe)
  Mike Froh (Cybersafe)
  Sasha Medvinsky (GI)
  Derek Atkins (Telcordia)

It must also be acknowledged that the Packetcable Security specification PKT-SP-SEC-I01-991201 provided the raw fodder for this effort in its Kerberized IPsec section, and all of the focus team members who played a part in the spec. We must also acknowledge Nancy Davoust of Cablelabs for keeping order in our normally disorderly proceedings.
