Abstract

This document provides a set of "torture tests" for implementers of the Signaling Compression (SigComp) protocol. The torture tests check each of the SigComp Universal Decompressor Virtual Machine instructions in turn, focusing in particular on the boundary and error cases that are not generally encountered when running well-behaved compression algorithms. Tests are also provided for other SigComp entities such as the dispatcher and the state handler.

1. Introduction

This document provides a set of "torture tests" for implementers of the SigComp protocol, RFC 3320 [2]. The idea behind SigComp is to standardize a Universal Decompressor Virtual Machine (UDVM) that can be programmed to understand the output of many well-known compressors including DEFLATE and LZW. The bytecode for the chosen decompressor is uploaded to the UDVM as part of the SigComp message flow.

The SigComp User’s Guide [1] gives examples of a number of different algorithms that can be used by the SigComp protocol. However, the bytecode for the corresponding decompressors is relatively well behaved and does not test the boundary and error cases that may potentially be exploited by malicious SigComp messages.

This document is divided into a number of sections, each containing a piece of code designed to test a particular function of one of the SigComp entities (UDVM, dispatcher, and state handler). The specific boundary and error cases tested by the bytecode are also listed, as are the output the code should produce and the number of UDVM cycles that should be used.

Each test runs in the SigComp minimum decompression memory size (that is, 2K), within the minimum number of cycles per bit (that is, 16) and in tests where state is stored 2K state memory size is needed.
2. Torture Tests for UDVM

The following sections each provide code to test one or more UDVM instructions. In the interests of readability, the code is given using the SigComp assembly language: a description of how to convert this assembly code into UDVM bytecode can be found in the SigComp User's Guide [1].

The raw UDVM bytecode for each torture test is given in Appendix A.

Each section also lists the number of UDVM cycles required to execute the code. Note that this figure only takes into account the cost of executing each UDVM instruction (in particular, it ignores the fact that the UDVM can gain extra cycles as a result of inputting more data).

2.1. Bit Manipulation

This section gives assembly code to test the AND, OR, NOT, LSHIFT, and RSHIFT instructions. When the instructions have a multitype operand, the code tests the case where the multitype contains a fixed integer value, and the case where it contains a memory address at which the 2-byte operand value can be found. In addition, the code is designed to test that the following boundary cases have been correctly implemented:

1. The instructions overwrite themselves with the result of the bit manipulation operation, in which case execution continues normally.

2. The LSHIFT or RSHIFT instructions shift bits beyond the 2-byte boundary, in which case the bits must be discarded.

3. The UDVM registers byte_copy_left and byte_copy_right are used to store the results of the bit manipulation operations. Since no byte copying is taking place, these registers should behave in exactly the same manner as ordinary UDVM memory addresses.

at (128)

JUMP (start) ; Jump to address 255

at (255)

:start

; The multitypes are values

$start = 448 (first 2 bytes of AND instr)

AND ($start, 21845) ; 448 & 21845 = 320 = 0x0140
OR ($a, 42)       ; 0 | 42 = 42 = 0x002a
NOT ($b)          ; ~0 = 65535 = 0xffff
LSHIFT ($a, 3)    ; 42 << 3 = 336 = 0x0150
RSHIFT ($b, 65535) ; 65535 >> 65535 = 0 = 0x0000

OUTPUT (64, 4) ; Output 0x0150 0000

; The multitypes are references

AND ($a, $start) ; 336 & 320 = 320 = 0x0140
OR ($a, $a)       ; 320 | 320 = 320 = 0x0140
NOT ($a)          ; ~320 = 65215 = 0xfebf
LSHIFT ($b, $a)   ; 0 << 65215 = 0 = 0x0000
RSHIFT ($a, $b)   ; 65215 >> 0 = 65215 = 0xfebf

OUTPUT (64, 4) ; Output 0xfebf 0000

END-MESSAGE (0, 0, 0, 0, 0, 0, 0)

The output of the code is 0x0150 0000 febf 0000. Executing the code costs a total of 22 UDVM cycles.

2.2. Arithmetic

This section gives assembly code to test the ADD, SUBTRACT, MULTIPLY, DIVIDE, and REMAINDER instructions. The code is designed to test that the following boundary cases have been correctly implemented:

1. The instructions overwrite themselves with the result of the arithmetic operation, resulting in continuation as if the bytes were not bytecode.
2. The result does not lie between 0 and $2^{16} - 1$ inclusive, in which case it must be taken modulo $2^{16}$.

3. The divisor in the DIVIDE or REMAINDER instructions is 0 (in which case decompression failure must occur).

```plaintext
:decomp_failure
DECOMPRESSION-FAILURE
```

; Now the value in $type$ should be 0xffff, 0x0000, or 0x0001 according to whether the input was 0x00, 0x01, or 0x02.

```plaintext
.add $start, 63809   ; 1728 + 63809 = 0x0001
.subtract $a, 1       ; 0 - 1 = 65535 = 0xffff
.multiply $a, 1001     ; 65535 * 1001 = 64535 = 0x0fc17
.divide $a, 101        ; 64535 / 101 = 638 = 0x027e
.remainder $a, 11      ; 638 % 11 = 0 = 0x0000
.output (64, 4)         ; output 0x0000 0000
```

; The multitypes are references
```plaintext
.add $b, $start       ; 0 + 1 = 1 = 0x0001
; If the message is 0x00
.subtract ($b, $type) ; 1 - 65535 = 2 = 0x0002
.multiply ($b, $b)    ; 2 * 2 = 4 = 0x0004
.divide ($a, $b)      ; 0 / 4 = 0 = 0x0000
.remainder ($b, $type) ; 4 % 65535 = 4 = 0x0004
```
OUTPUT (64, 4) ; output 0x0000 0004

; If the message is 0x01, $type = 0
; so decompression failure occurs at
; REMAINDER ($b, $type)

; If the message is 0x02, $type = 1 so
; $b becomes 0 and decompression failure
; occurs at DIVIDE ($a, $b)

END-MESSAGE (0, 0, 0, 0, 0, 0, 0)

If the compressed message is 0x00, then the output of the code is
0x0000 0000 0000 0004 and the execution cost should be 25 UDVM
cycles. However, if the compressed message is 0x01 or 0x02, then
decompression failure occurs.

2.3. Sorting

This section gives assembly code to test the SORT-ASCENDING and SORT-
DESCENDING instructions. The code is designed to test that the
following boundary cases have been correctly implemented:

1. The sorting instructions sort integers with the same value, in
which case the original ordering of the integers must be
preserved.

at (128)

SORT-DESCENDING (256, 2, 23)

2e, and the number of cycles required is 371.
2.4. SHA-1

This section gives assembly code to test the SHA-1 instruction. The code performs four tests on the SHA-1 algorithm itself and, in addition, checks the following boundary cases specific to the UDVM:

1. The input string for the SHA-1 hash is obtained by byte copying over an area of the UDVM memory.

2. The SHA-1 hash overwrites its own input string.

:byte_copy_left pad (2)

The output of the code is as follows:

0xa999 3e36 4706 816a ba3e 2571 7850 c26c 9cd0 d89d
0x8498 3e44 1c3b d26e baae 4aa1 f951 29e5 e546 70f1
0x12ff 347b 4f27 d69e 1f32 8e6f 4b55 73e3 666e 122f
0x4f46 0452 ebb5 6393 4f46 0452 ebb5 6393 4f46 0452

Executing the code costs a total of 17176 UDVM cycles.

2.5. LOAD and MULTILOAD

This section gives assembly code to test the LOAD and MULTILOAD instructions. The code is designed to test the following boundary cases:

1. The MULTILOAD instruction overwrites itself or any of its operands, in which case decompression failure occurs.

2. The memory references of MULTILOAD instruction operands are evaluated step-by-step rather than all at once before starting to copy data.

at (64)

:start                pad (1)
:start_lsb            pad (1)

at (128)

set (location_a, 128)
set (location_b, 132)
LOAD (128, 132) ; address 128 contains 132 = 0x0084
LOAD (130, $location_a) ; address 130 contains 132 = 0x0084
LOAD ($location_a, 134) ; address 132 contains 134 = 0x0086
LOAD ($location_b, $location_b) ; address 134 contains 134 = 0x0086
OUTPUT (128, 8) ; output 0x0084 0084 0086 0086

INPUT-BYTES (1, start_lsb, decompression_failure)
MULTIPLY ($start, 2)
ADD ($start, 60)
MULTILOAD ($start, 3, overlap_start, overlap_end, 128)

:position
set (overlap_start, (position - 7))
MULTILOAD ($start, 4, 42, 128, $location_a, $location_b)
:end
set (overlap_end, (end - 1))
OUTPUT (128, 8)
END-MESSAGE (0, 0, 0, 0, 0, 0, 0)
:decompression_failure
DECOMPRESSION-FAILURE

The INPUT-BYTES, MULTIPLY, and ADD instructions give the following values for $start = $64 just before the MULTILOADs begin:

<table>
<thead>
<tr>
<th>Input</th>
<th>$start before 1st MULTILOAD</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x00</td>
<td>60</td>
</tr>
<tr>
<td>0x01</td>
<td>62</td>
</tr>
<tr>
<td>0x02</td>
<td>64</td>
</tr>
</tbody>
</table>

Consequently, after the first MULTILOAD the values of $start are the following:

<table>
<thead>
<tr>
<th>Input</th>
<th>$start before 2nd MULTILOAD</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x00</td>
<td>128</td>
</tr>
<tr>
<td>0x01</td>
<td>overlap_end = 177 = last byte of 2nd MULTILOAD instruction</td>
</tr>
<tr>
<td>0x02</td>
<td>overlap_start = 162 = 7 bytes before 2nd MULTILOAD instruction</td>
</tr>
</tbody>
</table>
Consequently, execution of the 2nd MULTILOAD (and any remaining code) gives the following:

<table>
<thead>
<tr>
<th>Input</th>
<th>Outcome</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x00</td>
<td>MULTILOAD reads and writes operand by operand. The output is 0x0084 0084 0086 0086 002a 0080 002a 002a, and the cost of executing the code is 36 UDVM cycles.</td>
</tr>
<tr>
<td>0x01</td>
<td>The first write of the MULTILOAD instruction would overwrite the last byte of the final MULTILOAD operand, so decompression failure occurs.</td>
</tr>
<tr>
<td>0x02</td>
<td>The last write of the MULTILOAD would overwrite the MULTILOAD opcode, so decompression failure occurs.</td>
</tr>
</tbody>
</table>

2.6. COPY

This section gives assembly code to test the COPY instruction. The code is designed to test that the following boundary cases have been correctly implemented:

1. The COPY instruction copies data from both outside the circular buffer and inside the circular buffer within the same operation.

2. The COPY instruction performs byte-by-byte copying (i.e., some of the later bytes to be copied are themselves written into the UDVM memory by the COPY instruction currently being executed).

3. The COPY instruction overwrites itself and continues executing.

4. The COPY instruction overwrites the UDVM registers byte_copy_left and byte_copy_right.

5. The COPY instruction writes to and reads from the right of the buffer beginning at byte_copy_right.

6. The COPY instruction implements byte copying rules when the destination wraps around the buffer.

at (64)

:byte_copy_left pad (2)
:byte_copy_right pad (2)
at (128) ; Set up buffer between addresses 64 & 128
LOAD (32, 16384)

; the buffer, into the buffer and wrapping
; the buffer (inc overwriting the
; boundaries)
LOAD (64, 16640) ; Change the start of the buffer to be
; beyond bytecode
COPY (64, 85, 65) ; Copy to the left of the buffer,
; overwriting this instruction
OUTPUT (32, 119) ; Output 32 * 0x40 + 86 * 0x41 + 0x55,
; which is 32 * '@' + 86 'A' + 'U'
; Set a new small buffer
LOAD (byte_copy_left, 32)
LOAD (byte_copy_right, 48)
MEMSET (32, 4, 65, 1) ; Set first 4 bytes of the buffer to be
; 'ABCD'
COPY (32, 4, 48) ; Copy from byte_copy_right (i.e., not
; in buffer)
OUTPUT (48, 4) ; Output 0x4142 4344, which is 'ABCD'
COPY (48, 4, 46) ; Copy from two before byte_copy_right to
; wrap around the buffer
OUTPUT (32, 2) ; Output 0x4344, which is 'CD'

END-MESSAGE (0, 0, 0, 0, 0, 0, 0)

The output is above, and executing the code costs a total of 365 UDVM cycles.

2.7. COPY-LITERAL and COPY-OFFSET

This section gives assembly code to test the COPY-LITERAL and COPY-OFFSET instructions. The code is designed to test similar boundary cases to the code for the COPY instruction, as well as the following condition specific to COPY-LITERAL and COPY-OFFSET:
1. The COPY-LITERAL or COPY-OFFSET instruction overwrites the value of its destination.

2. The COPY-OFFSET instruction reads from an offset that wraps around the buffer (i.e., the offset is larger than the distance between byte_copy_left and the destination).

```plaintext
at (64)
:byte_copy_left       pad (2)
:byte_copy_right      pad (2)
:destination          pad (2)
:offset               pad (2)

at (128)
; Set up circular buffer, source, and destination
LOAD (32, 16640)
LOAD (byte_copy_left, 64)
LOAD (byte_copy_right, 128)
LOAD (destination, 33)

COPY-LITERAL (32, 128, $destination) ; Copy from the left of the buffer overwriting bcl, bcr, and destination wrapping around the buffer
OUTPUT (64, 8) ; Check destination has been updated
    ; Output 0x4141 4141 0061 4141

LOAD (destination, copy)
:copy                   ; Overwrite the copy instruction
COPY-LITERAL (32, 2, $destination)
OUTPUT (copy, 2)        ; Output 0x4141

LOAD (byte_copy_left, 72) ; Set up new circular buffer
LOAD (byte_copy_right, 82)
LOAD (destination, 82) ; Set destination to byte_copy_right

MEMSET (72, 10, 65, 1) ; Fill the buffer with 0x41 - 4A

COPY-OFFSET (2, 6, $destination) ; Copy from within circular buffer to outside buffer

LOAD (offset, 6)
COPY-OFFSET ($offset, 4, $destination)
    ; Copy from byte_copy_right
    ; so reading outside buffer
```
OUTPUT ($byte_copy_right, 10) ; Output 0x494A 4142 4344 494A 4142, ; which is 'IJABCDIJAB'
LOAD (destination, 80) ; Put destination within the buffer
COPY-OFFSET (4, 4, $destination) ; Copy where destination wraps
OUTPUT (destination, 2) ; Output 0x004A
COPY-OFFSET (5, 4, $destination) ; Copy where offset wraps from left back around to the right
OUTPUT (destination, 2) ; Output 0x004E
OUTPUT ($byte_copy_left, 10) ; Output the circular buffer 0x4748 4845 4647 4748 4546, ; which is 'GHHEFGGHEF'

END-MESSAGE (0, 0, 0, 0, 0, 0, 0)

The output of the code is above, and the cost of execution is 216 UDVM cycles.

2.8. MEMSET

This section gives assembly code to test the MEMSET instruction. The code is designed to test that the following boundary cases have been correctly implemented:

1. The MEMSET instruction overwrites the registers byte_copy_left and byte_copy_right.

2. The output values of the MEMSET instruction do not lie between 0 and 255 inclusive (in which case they must be taken modulo 2^8).

at (64)
:byte_copy_left pad (2)
:byte_copy_right pad (2)

at (128)

LOAD (byte_copy_left, 128) ; sets up a circular buffer
LOAD (byte_copy_right, 129) ; of 1 byte between 0x0080 and 0x0081

MEMSET (64, 129, 0, 1) ; fills up the memory in the range 0x0040-0x007f with 0x00, ... 0x3f; then it writes successively at 0x0080 the following values 0x40, ... 0x80; as a side effect, the values of bcl and bcr are modified.
before and during the MEMSET:
byte_copy_left: 0x0080 byte_copy_right: 0x0081
after the MEMSET:
byte_copy_left: 0x0001 byte_copy_right: 0x0203

MEMSET (129, 15, 64, 15) ; fills the memory range 0x0080-0x008f
; with values 0x40, 0x4f, ... 0xf4, 0x03, 0x12.
; as a side effect, it overwrites a
; part of the code including itself

OUTPUT (128, 16) ; outputs 0x8040 4f5e 6d7c 8b9a
; a9b8 c7d6 e5f4 0312

END-MESSAGE (0, 0, 0, 0, 0, 0, 0)

The output of the code is 0x8040 4f5e 6d7c 8b9a a9b8 c7d6 e5f4 0312.
Executing the code costs 166 UDVM cycles.

2.9. CRC

This section gives assembly code to test the CRC instruction. The
code does not test any specific boundary cases (as there do not
appear to be any) but focuses instead on verifying the CRC algorithm.

at (64)
:byte_copy_left pad (2)
:byte_copy_right pad (2)

; 0x81, ... 0x93

INPUT-BYTES (2, crc_value, decompression_failure)
; reads in 2 bytes representing
; the CRC value of the byte string
; of 44 bytes starting at 0x0046
CRC ($crc_value, crc_string_a, 44, decompression_failure) ; computes the CRC value of the ; byte string crc_string_a ; concatenated with byte string ; crc_string_b (with a total ; length of 44 bytes). ; if the computed value does ; not match the 2-byte value read ; previously, the program ends ; with DECOMPRESSION-FAILURE.

END-MESSAGE (0, 0, 0, 0, 0, 0, 0)

:decompression_failure
DECOMPRESSION-FAILURE

If the compressed message is 0x62cb, then the code should successfully terminate with no output, and with a total execution cost of 95 UDVM cycles. For different 2-byte compressed messages, the code should terminate with a decompression failure.

2.10. INPUT-BITS

This section gives assembly code to test the INPUT-BITS instruction. The code is designed to test that the following boundary cases have been correctly implemented:

1. The INPUT-BITS instruction changes between any of the four possible bit orderings defined by the input_bit_order register.

2. The INPUT-BITS instruction inputs 0 bits.

3. The INPUT-BITS instruction requests data that lies beyond the end of the compressed message.

at (64)

:byte_copy_left          pad (2)
:byte_copy_right         pad (2)
:input_bit_order         pad (2)
:result                   pad (2)
INPUT-BITS ($input_bit_order, result, end_of_message) ; reads in
; exactly as many bits as the 2-byte
; value written in the input_bit_order
; register, get out of the loop when
; no more bits are available at input.

OUTPUT (result, 2) ; outputs as a 2-byte integer
; the previously read bits

ADD ($input_bit_order, 1) ; if at the beginning of this loop the
; register input_bit_order is 0,
REMAINDER ($input_bit_order, 7) ; then its value varies periodically
; like this: 2, 4, 6, 1, 3, 5, 7.
ADD ($input_bit_order, 1) ; that gives for the FHP bits: 010,
; 100, 110, 001, 011, 101, 111
JUMP (start) ; run the loop once more

END-MESSAGE (0, 0, 0, 0, 0, 0, 0)

An example of a compressed message is 0x932e ac71, which decompresses
to give the output 0x0000 0002 0002 0013 0000 0003 001a 0038. Executing the code costs 66 UDVM cycles.

2.11. INPUT-HUFFMAN

This section gives assembly code to test the INPUT-HUFFMAN
instruction. The code is designed to test that the following
boundary cases have been correctly implemented:

1. The INPUT-HUFFMAN instruction changes between any of the four
   possible bit orderings defined by the input_bit_order register.

2. The INPUT-HUFFMAN instruction inputs 0 bits.

3. The INPUT-HUFFMAN instruction requests data that lies beyond the
   end of the compressed message.
An example of a compressed message is 0x932e ac71 66d8 6f, which decompresses to give the output 0x0000 0003 0008 04d7 0002 0003 0399 30fe. Executing the code costs 84 UDVM cycles.

As the code is run, the input_bit_order changes through all possible values to check usage of the H and P bits. The number of bits to input each time is taken from the value of input_bit_order. The sequence is the following:

<table>
<thead>
<tr>
<th>Input_bit_order (bin)</th>
<th>Total bits input by Huffman</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>010</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>100</td>
<td>4</td>
<td>8</td>
</tr>
<tr>
<td>110</td>
<td>12</td>
<td>1239</td>
</tr>
<tr>
<td>001</td>
<td>P-bit changed, throw away 6 bits</td>
<td></td>
</tr>
<tr>
<td>001</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>011</td>
<td>3</td>
<td>3</td>
</tr>
<tr>
<td>101</td>
<td>10</td>
<td>921</td>

<tr>
<td>111</td>
<td>14</td>
<td>12542</td>
</tr>
<tr>
<td>010</td>
<td>P-bit changed, throw away 4 bits</td>
<td></td>
</tr>
<tr>
<td>010</td>
<td>0 - not enough bits so terminate</td>
<td></td>
</tr>
</tbody>
</table>

An example of a compressed message is 0x932e ac71 66d8 6f, which decompresses to give the output 0x0000 0003 0008 04d7 0002 0003 0399 30fe. Executing the code costs 84 UDVM cycles.

As the code is run, the input_bit_order changes through all possible values to check usage of the H and P bits. The number of bits to input each time is taken from the value of input_bit_order. The sequence is the following:

<table>
<thead>
<tr>
<th>Input_bit_order (bin)</th>
<th>Total bits input by Huffman</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>010</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>100</td>
<td>4</td>
<td>8</td>
</tr>
<tr>
<td>110</td>
<td>12</td>
<td>1239</td>
</tr>
<tr>
<td>001</td>
<td>P-bit changed, throw away 6 bits</td>

<td>2</td>
</tr>
<tr>
<td>011</td>
<td>3</td>
<td>3</td>
</tr>
<tr>
<td>101</td>
<td>10</td>
<td>921</td>
</tr>
<tr>
<td>111</td>
<td>14</td>
<td>12542</td>
</tr>
<tr>
<td>010</td>
<td>P-bit changed, throw away 4 bits</td>
<td></td>
</tr>
<tr>
<td>010</td>
<td>0 - not enough bits so terminate</td>
<td></td>
</tr>
</tbody>
</table>
2.12.  INPUT-BYTES

This section gives assembly code to test the INPUT-BYTES instruction. The code is designed to test that the following boundary cases have been correctly implemented:

1. The INPUT-BYTES instruction inputs 0 bytes.

2. The INPUT-BYTES instruction requests data that lies beyond the end of the compressed message.

3. The INPUT-BYTES instruction is used after part of a byte has been input (e.g., by the INPUT-BITS instruction).

at (64)

:byte_copy_left       pad (2)
:byte_copy_right      pad (2)
:input_bit_order      pad (2)
:result               pad (2)
:output_start         pad (4)
:output_end

at (128)

LOAD (byte_copy_left, output_start)
LOAD (byte_copy_right, output_end)

:start

INPUT-BITS ($input_bit_order, result, end_of_message)
OUTPUT (result, 2)

ADD ($input_bit_order, 2)
REMAINDER ($input_bit_order, 7)

INPUT-BYTES ($input_bit_order, output_start, end_of_message)
OUTPUT (output_start, $input_bit_order)

ADD ($input_bit_order, 1)
JUMP (start)

:end_of_message

END-MESSAGE (0, 0, 0, 0, 0, 0, 0, 0)
An example of a compressed message is 0x932e ac71 66d8 6fb1 592b dc9a 9734 d847 a733 874e 1bcb cd51 b5dc 9659 9d6a, which decompresses to give the output 0x0000 932e 0001 b166 d866 b100 1a2b 0003 9a97 34d8 0007 0001 3387 4e00 08dc 9651 b5dc 9600 599d 6a. Executing the code costs 130 UDVM cycles.

As the code is run, the input_bit_order changes through all possible values to check usage of the F and P bits. The number of bits or bytes to input each time is taken from the value of input_bit_order. For each INPUT-BYTES instruction, the remaining bits of the byte are thrown away. The P-bit always changes on the byte boundary so no bits are thrown away. The sequence is the following:

<table>
<thead>
<tr>
<th>Input_bit_order (bin)</th>
<th>Input bits</th>
<th>Input bytes</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>0</td>
<td>0</td>
<td>0x0000</td>

2.13. Stack Manipulation

This section gives assembly code to test the PUSH, POP, CALL, and RETURN instructions. The code is designed to test that the following boundary cases have been correctly implemented:

1. The stack manipulation instructions overwrite the UDVM register stack_location.

2. The CALL instruction specifies a reference operand rather than an absolute value.

3. The PUSH instruction pushes the value contained in stack_fill onto the stack.

4. The stack_location register contains an odd integer.

SWITCH (4, $switch_counter, address_g, $next_address, address_c, address_e)  
; when $switch_counter = 1,  
; $next_address gives jump to  
; address_a  

:address_g  

END-MESSAGE (0, 0, 0, 0, 0, 0, 0)  

The output of the code is 0x0001 0102 0203 0304 0405 0506 0707 0708 0808 0909, and a total of 131 UDVM cycles are used.

2.15. State Creation

This section gives assembly code to test the STATE-CREATE and STATE-FREE instructions. The code is designed to test that the following boundary cases have been correctly implemented:

1. An item of state is created that duplicates an existing state item.

2. An item of state is freed when the state has not been created.

3. An item of state is created and then freed by the same message.

4. The STATE-FREE instruction frees a state item by sending fewer bytes of the state_identifier than the minimum_access_length.
5. The STATE-FREE instruction has partial_identifier_length operand shorter than 6 or longer than 20.

6. The STATE-FREE instruction specifies a partial_identifier that matches with two state items in the compartment.

7. The bytes of the identifier are written to the position specified in the STATE-FREE instruction after the STATE-FREE instruction has been run (and before END-MESSAGE).

2.16. STATE-ACCESS

This section gives assembly code to test the STATE-ACCESS instruction. The code is designed to test that the following boundary cases have been correctly implemented:

1. A subset of the bytes contained in a state item is copied to the UDVM memory.

2. Bytes are copied from beyond the end of the state value.

3. The state_instruction operand is set to 0.

4. The state cannot be accessed because the partial state identifier is too short.

5. The state identifier is overwritten by the state item being accessed.

The following bytecode needs to be run first to set up the state for the rest of the test.
END-MESSAGE (0, 0, state_length, state_start, 0, 20, 0)

; The bytes between state_start and state_end are derived from
; translation of the following mnemonic code:
; at (512)
; OUTPUT (data, 4)
; END-MESSAGE (0,0,0,0,0,0)
; :data
; byte (116, 101, 115, 116)

:state_start
byte (34, 162, 12,4, 35, 0, 0, 0, 0, 0, 116, 101, 115, 116)

set (state_length, (state_end - state_start))

This is the bytecode for the rest of the test.

OUTPUT (state_value, 4)
JUMP (end)

:error_conditions
3. Torture Tests for Dispatcher

The following sections give code to test the various functions of the SigComp dispatcher.

3.1. Useful Values

This section gives assembly code to test that the SigComp "Useful Values" are correctly initialized in the UDVM memory. It also tests that the UDVM is correctly terminated if the bytecode uses too many UDVM cycles or tries to write beyond the end of the available memory.
The code tests that the following boundary cases have been correctly implemented:

1. The bytecode uses exactly as many UDVM cycles as are available (in which case no problems should arise) or one cycle too many (in which case decompression failure should occur). A liberal implementation could allow more cycles to be used than are strictly available, in which case decompression failure will not occur. This is an implementation choice. If this choice is made, the implementer must be sure that the cycles are checked eventually and that decompression failure does occur when bytecode uses an excessive number of cycles. This is tested in Section 3.2.

2. The bytecode writes to the highest memory address available (in which case no problems should arise) or to the memory address immediately following the highest available address (in which case decompression failure must occur).

```assembly

:test_udvm_memory

; Copy one byte to
; udvm_memory_size + input - 1
; Succeed when input byte is 0x00
; Fail when input byte is 0x01

INPUT-BYTES (1, check_memory_lsb, decompression_failure)
ADD ($check_memory, $udvm_memory_size)
SUBTRACT ($check_memory, 1)
COPY (32, 1, $check_memory)

:test_udvm_cycles

INPUT-BYTES (1, check_cycles_lsb, decompression_failure)

; Work out the total number of cycles available to the UDVM
; total_UDVM_cycles = cycles_per_bit * (8 * message_size + 1000)
;
; = cycles_per_bit * (8 * (partial_state_id_length + 3) + 1000)

LOAD (remaining_cycles, $partial_state_id_length)
ADD ($remaining_cycles, 3)
MULTIPLY ($remaining_cycles, 8)
ADD ($remaining_cycles, 1000)
MULTIPLY ($remaining_cycles, $cycles_per_bit)
ADD ($remaining_cycles, $check_cycles)
set (cycles_used_by_bytecode, 856)
The bytecode must be executed a total of four times in order to fully test the SigComp Useful Values. In the first case, the bytecode is uploaded as part of the SigComp message with a 1-byte compressed message corresponding to the version of SigComp being run. This causes the UDVM to request creation of a new state item and uses a total of 968 UDVM cycles.

Subsequent tests access this state by uploading the state identifier as part of the SigComp message. Note that the SigComp message should not contain a returned feedback item (as this would cause the bytecode to calculate the total number of available UDVM cycles incorrectly).

A 3-byte compressed message is required for the second and subsequent cases, the first byte of which is the version of SigComp in use, 0xnn. If the message is 0xnn0000, then the UDVM should successfully terminate using exactly the number of available UDVM cycles. However, if the message is 0xnn0001, then the UDVM should use too many cycles and hence terminate with decompression failure. Furthermore, if the message is 0xnn0100, then decompression failure must occur because the UDVM attempts to write beyond its available memory.

### 3.2. Cycles Checking

As discussed in Section 3.1, it is possible to write an implementation that takes a liberal approach to checking the cycles used and allows some extra cycles. The implementer must be sure that decompression failure does not occur too early and that in the case of excessive use of cycles, decompression failure does eventually occur. This test checks that:

1. Decompression failure occurs eventually when there is an infinite loop.
MULTILOAD (byte_copy_left, 4, 32, 41, 0, 34)

; Set up a 10-byte buffer

; Set the value to copy
; Copy it 100 times,
; output the value,
; increment the counter

If the cycles are counted exactly and cycles per bit (cpb) = 16, then decompression failure will occur at COPY-OFFSET when value = 180 = 0xB4. If cpb = 32, then decompression failure will occur when value = 361 = 0x0169. If they are not counted exactly, then decompression failure MUST occur eventually.

3.3. Message-based Transport

This section provides a set of messages to test the SigComp header over a message-based transport such as UDP. The messages test that the following boundary cases have been correctly implemented:

1. The UDVM bytecode is copied to different areas of the UDVM memory.
2. The decompression memory size is set to an incorrect value.
3. The SigComp message is too short.
4. The destination address is invalid.

The basic version of the code used in the test is given below. Note that the code is designed to calculate the decompression memory size based on the Useful Values provided to the UDVM:
:udvm_memory_size pad (2)
:cycles_per_bit pad (2)
:sigcomp_version pad (2)
:partial_state_id_length pad (2)
:state_length pad (2)

at (128)

:code_start

; udvm_memory_size for message-based transport
; = DMS - total_message_size

ADD ($udvm_memory_size, total_message_size)
OUTPUT (udvm_memory_size, 2)
END-MESSAGE (0, 0, 0, 0, 0, 0, 1)

:code_end

set (header_size, 3)
set (code_size, (code_end - code_start))
set (total_message_size, (header_size + code_size))

A number of complete SigComp messages are given below, each containing some or all of the above code. In each case, it is indicated whether the message will successfully output the decompression memory size or whether it will cause a decompression failure to occur (together with the reason for the failure):

SigComp message: Effect:

0xf8 Fails (message too short)
0xf800 Fails (message too short)
0xf800 e106 0011 2200 0223 Outputs the decompression_memory_size
  0x0000 0000 0000 01
0xf800 f106 0011 2200 0223 Fails (message too short)
  0x0000 0000 0000 01
0xf800 e006 0011 2200 0223 Fails (invalid destination address)
  0x0000 0000 0000 01
0xf800 ee06 0011 2200 0223 Outputs the decompression_memory_size
  0x0000 0000 0000 01
The messages should be decompressed in the order given to check that an error in one message does not interfere with the successful decompression of subsequent messages.

The two messages that successfully decompress each use a total of 5 UDVM cycles.

3.4. Stream-based Transport

This section provides a byte stream to test the SigComp header and delimiters over a stream-based transport such as TCP. The byte stream tests all of the boundary cases covered in Section 3.2, as well as the following cases specific to stream-based transports:

1. Quoted bytes are used by the record marking scheme.

2. Multiple delimiters are used between the same pair of messages.

3. Unnecessary delimiters are included at the start of the stream.

The basic version of the code used in the test is given below. Note that the code is designed to calculate the decompression memory size based on the Useful Values provided to the UDVM:

```plaintext
:udvm_memory_size    pad (2)
:cycles_per_bit      pad (2)
:sigcomp_version     pad (2)
:partial_state_id_length pad (2)
:state_length        pad (2)

at (128)

; udvm_memory_size for stream based transport = DMS / 2

MULTIPLY ($udvm_memory_size, 2)
OUTPUT (udvm_memory_size, 2)
OUTPUT (test_record_marking, 5)
END-MESSAGE (0, 0, 0, 0, 0, 0, 0)

:test_record_marking

byte (255, 255, 255, 255, 255)
```
The above assembly code has been compiled and used to generate the following byte stream:

```
0xffff f801 7108 0002 2200 0222 a092 0523 0000 0000 00ff 00ff
0x03ff ffff ffff ffff f801 7e08 0002 2200 0222 a3d2 0523 0000 0000
0x0000 00ff 04ff ffff ffff ffff ff
```

Note that this byte stream can be divided into five distinct portions (two SigComp messages and three sets of delimiters) as illustrated below:

**Portion of byte stream:**                                **Meaning:**

```
0xffff                        Delimiter
```

```
0xf801 7108 0002 2200 0222 a092 0523                        First message
0x0000 00ff 04ff 03ff ffff
```

```
0xffff                        Delimiter
0xf801 7e08 0002 2200 0222 a3d2 0523                      Second message
0x0000 00ff 04ff 04ff ff
```

```
0xffff ffff                        Delimiter
```

When the complete byte stream is supplied to the decompressor dispatcher, the record marking scheme must use the delimiters to partition the stream into two distinct SigComp messages. Both of these messages successfully output the decompression memory size (as a 2-byte value), followed by 5 consecutive 0xff bytes to test that the record marking scheme is working correctly. A total of 11 UDVM cycles are used in each case.

It must also be checked that the dispatcher can handle the same error cases as covered in Section 3.2. Each of the following byte streams should cause a decompression failure to occur for the reason stated:

**Byte stream:**                                **Reason for failure:**

```
0xf80f ff                              Message too short
0xf800 ffff                             Message too short
0xf801 8108 0002 2200 0222 a092 0523 ffff Message too short
0x0000 00ff 00ff 03ff ffff
0xf801 7008 0002 2200 0222 a092 0523 ffff Invalid destination
0x0000 00ff 04ff 04ff ff
```
3.5. Input Past the End of a Message

This section gives assembly code to test that the implementation correctly handles input past the end of a SigComp message. The code is designed to test that the following boundary cases have been correctly implemented:

1. An INPUT instruction requests data that lies beyond the end of the message. In this case, the dispatcher should not return any data to the UDVM. Moreover, the message bytes held by the dispatcher should still be available for retrieval by subsequent INPUT instructions.

2. The INPUT-BYTES instruction is used after part of a byte has been input (e.g., by the INPUT-BITS instruction). In this case, the remaining partial byte must be discarded, even if the INPUT-BYTES instruction requests data that lies beyond the end of the message.

at (64)

:byte_copy_left    pad (2)
:byte_copy_right   pad (2)
:input_bit_order   pad (2)
:result            pad (1)
:result_lsb        pad (6)
:right

at (128)

LOAD (byte_copy_left, result)
LOAD (byte_copy_right, right)

:start

; Input bits to ensure that the remaining message is not byte aligned
INPUT-BITS (9, result, decompression_failure1) ; Input 0x1FF (9 bits)

; Attempt to read 7 bytes
INPUT-BYTES (7, result, next_bytes) ; This should fail, throw away 
; 7 bits with value Ox7a and 
; jump to next_bytes

:decompression_failure1
DECOMPRESSION-FAILURE ; This instruction is never 
; executed but is used to 
; separate success and failure 
; to input bytes.

:next_bytes
; Read 7 bits - this removes the byte alignment of the message
; If the bits have not been thrown away where they should be, then
; the message will be 1 byte longer than necessary and the output
; will be incorrect.

INPUT-BITS (7, result, decomposition_failure1) ; Input 0x00 (7 bits)
; Read 2 bytes

INPUT-BYTES (2, result, decomposition_failure1)
; Throw away 1 bit value 0
; Input 0x6869
OUTPUT (result, 2)
; Output 0x6869

INPUT-BITS (16, result, bits) ; Attempt to read more bits than
; there are to ensure they
; remain available

:decompression_failure2
DECOMPRESSION-FAILURE ; This instruction is never 
; executed but is used to 
; separate success and failure 
; to input bits.

:bits
; Read 8 bits

INPUT-BITS (8, result, decomposition_failure2) ; Input 0x21 or fail
OUTPUT (result_lsb, 1) ; Output 0x21

:end_message

END-MESSAGE (0, 0, 0, 0, 0, 0, 0)
If the compressed message is 0xfffa 0068 6921, then the code terminates successfully with the output 0x6869 21, and a total of 23 UDVM cycles are used. However, if the compressed message is 0xfffa 0068 69, then decompression failure occurs (at the final INPUT-BITS).

4. Torture Tests for State Handler

The following sections give code to test the various functions of the SigComp state handler.

4.1. SigComp Feedback Mechanism

This section gives assembly code to test the SigComp feedback mechanism. The code is designed to test that the following boundary cases have been correctly implemented:

1. Both the short and the long versions of the SigComp feedback item are used.

2. The chain of returned SigComp parameters is terminated by a non-zero value.

at (64)

: type pad (1)
: type_lsb pad (1)

: requested_feedback_location pad (1)
: requested_feedback_length pad (1)
: requested_feedback_bytes pad (127)

: returned_parameters_location pad (2)
: length_of_partial_state_id_a pad (1)
: partial_state_identifier_a pad (6)
: length_of_partial_state_id_b pad (1)
: partial_state_identifier_b pad (12)
: length_of_partial_state_id_c pad (1)
: partial_state_identifier_c pad (20)
: terminate_returned_parameters pad (1)

align (128)

set (q_bit, 1)
set (s_bit, 0)

JUMP (return_sigcomp_parameters)

:long_feedback_item

set (requested_feedback_field, 255)
set (long_feedback_value, ((flags * 256) + requested_feedback_field))

LOAD (requested_feedback_location, long_feedback_value)
MEMSET (requested_feedback_bytes, 127, 1, 1)

:return_sigcomp_parameters

set (cpb, 0)
set (dms, 1)
set (sms, 0)
set (sigcomp_version, 1)

set (parameters_msb, (((64 * cpb) + (8 * dms)) + sms))
set (sigcomp_parameters, ((256 * parameters_msb) + sigcomp_version))

LOAD (returned_parameters_location, sigcomp_parameters)

LOAD (length_of_partial_state_id_a, 1536) ; length 6 first byte 0
LOAD (length_of_partial_state_id_b, 3072) ; length 12 first byte 0
LOAD (length_of_partial_state_id_c, 5120) ; length 20 first byte 0
LOAD (terminate_returned_parameters, 5376) ; length 21
     ; used to terminate the
     ; returned parameters

MEMSET (partial_state_identifier_a, 6, 0, 1)
MEMSET (partial_state_identifier_b, 12, 0, 1)
MEMSET (partial_state_identifier_c, 20, 0, 1)

END-MESSAGE (requested_feedback_location, returned_parameters_location, 0, 0, 0, 0, 0)
:decompression_failure
DECOMPRESSION-FAILURE
When the above code is executed, it supplies a requested feedback item to the state handler. If the compressed message is 0x00, then the short (1-byte) version of the feedback is used. Executing the bytecode in this case costs a total of 52 UDVM cycles. Assuming that the feedback request is successful, the feedback item should be returned in the first SigComp message to be sent in the reverse direction. The SigComp message returning the feedback should begin as follows:

```
+---+---+---+---+---+---+---+---+
| 1   1   1   1   1   1 |   X   |     first header byte
+---+---+---+---+---+---+---+---+
| 0 |            127            |     returned feedback field
+---+---+---+---+---+---+---+---+
```

So the first 2 bytes of the returning SigComp message should be 0xfn7f where n = c, d, e, or f (the choice of n is determined by the compressor generating the returning SigComp message, which is not under the control of the above code).

If the compressed message is 0x01, then the long version of the feedback item is used. Executing the bytecode in this case costs a total of 179 UDVM cycles and the SigComp message returning the feedback should begin as follows:

```
+---+---+---+---+---+---+---+---+
| 1   1   1   1   1   1 |   X   |     first header byte
+---+---+---+---+---+---+---+---+
| 1 |            127            |     returned feedback length
+---+---+---+---+---+---+---+---+
|               1               |     ^
+---+---+---+---+---+---+---+---+
|               2               |     |
+---+---+---+---+---+---+---+---+
|               3               |     returned feedback field
+---+---+---+---+---+---+---+---+
```

So the first 129 bytes of the SigComp message should be 0xfnff 0102 0304 ... 7e7f where n = c, d, e, or f as above.

As well as testing the requested and returned feedback items, the above code also announces values for each of the SigComp parameters. The supplied version of the code announces only the minimum possible values for the cycles_per_bit, decompression_memory_size, state_memory_size, and SigComp_version (although this can easily be adjusted to test different values for these parameters).
The code should also announce the availability of state items with the following partial state identifiers:

0x0001 0203 0405
0x0001 0203 0405 0607 0809 0a0b
0x0001 0203 0405 0607 0809 0a0b 0c0d 0e0f 1011 1213

Note that different implementations may make use of the announcement information in different ways. It is a valid implementation choice to simply ignore all of the announcement data and use only the minimum resources that are guaranteed to be available to all endpoints. However, the above code is useful for checking that an endpoint interprets the announcement data correctly (in particular ensuring that it does not mistakenly use resources that have not in fact been announced).

4.2. State Memory Management

The following section gives assembly code to test the memory management features of the state handler. The code checks that the correct states are retained by the state handler when insufficient memory is available to store all of the requested states.

The code is designed to test that the following boundary cases have been correctly implemented:

1. A state item is created that exceeds the total state_memory_size for the compartment.
2. States are created with a non-zero state_retention_priority.
3. A new state item is created that has a lower state_retention_priority than existing state items in the compartment.

For the duration of this test, it is assumed that all states will be saved in a single compartment with a state_memory_size of 2048 bytes.

```assembly
at (64)

:byte_copy_left       pad (2)
:byte_copy_right      pad (2)
:order                pad (2)
:type                 pad (1)
:type_lsb             pad (1)
:state_length         pad (2)
:state_retention_priority   pad (2)
```
MULTILOAD (byte_copy_left, 2, state_start, order_data)

INPUT-BYTES (1, type_lsb, decompression_failure)

:state_identifier_c

byte (35, 154, 52, 107, 21, 166)
The above code must be executed a total of 7 times in order to complete the test. Each time the code is executed, a 1-byte compressed message should be provided as below. The effects of the messages are given below. States are described in the form (name, x, y) where name corresponds to the name of the identifier in the mnemonic code, x is the length of the state, and y is the retention priority of the state.

<table>
<thead>
<tr>
<th>Message</th>
<th>Effect</th>
<th>#cycles</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x00</td>
<td>create states: (a,0,0), (b,256,1), (c,512,2)</td>
<td>811</td>
</tr>
<tr>
<td>0x01</td>
<td>create states: (d,768,3), (e,1024,4) - deleting a, b, c</td>
<td>2603</td>
</tr>
<tr>
<td>0x02</td>
<td>create states: (c,512,2), - deleting d (b,256,1), (a,0,0)</td>
<td>811</td>
</tr>
<tr>
<td>0x03</td>
<td>access states a,b,c,e</td>
<td>1805</td>
</tr>
<tr>
<td>0x04</td>
<td>access state d - not present so decompression failure</td>
<td></td>
</tr>
<tr>
<td>0x05</td>
<td>create states: (large, 2048,0) - deleting a, b, c, e</td>
<td>2057</td>
</tr>
<tr>
<td>0x06</td>
<td>access large state</td>
<td>1993</td>
</tr>
</tbody>
</table>

Note that as new states are created, some of the existing states will be pushed out of the compartment due to lack of memory.

4.3. Multiple Compartments

This section gives assembly code to test the interaction between multiple SigComp compartments. The code is designed to test that the following boundary cases have been correctly implemented:
1. The same state item is saved in more than one compartment.

2. A state item stored in multiple compartments has the same state identifier but a different state_retention_priority in each case.

3. A state item is deleted from one compartment but still belongs to a different compartment.

4. A state item belonging to multiple compartments is deleted from every compartment to which it belongs.

The test requires a total of three compartments to be available, which will be referred to as Compartment 0, Compartment 1, and Compartment 2. Each of the three compartments should have a state_memory_size of 2048 bytes.

The assembly code for the test is given below:

```assembly
at (64)
:byte_copy_left       pad (2)

The above code must be executed a total of 9 times in order to complete the test. Each time the code is executed, a 1-byte compressed message $N$ should be provided, taking the values 0x00 to 0x08 in ascending order (so the compressed message should be 0x00 the first time the code is run, 0x01 the second, and so on).

If the code makes a state creation request, then the state must be saved in Compartment (N modulo 3).

When the compressed message is 0x00, 0x01, or 0x02, the code makes four state creation requests in compartments 0, 1, and 2, respectively. This creates a total of seven distinct state items referred to as State a through State g. The states should be distributed among the three compartments as illustrated in Figure 1 (note that some states belong to more than one compartment).

When the compressed message is 0x03 or 0x04, the code overwrites all of the states in Compartments 0 and 1, respectively. This means that States a, b, and e will be unavailable because they are no longer present in any of the three compartments.

When the compressed message is 0x05, the code checks that the States c, d, f, and g are still available. Decompression should terminate successfully in this case.

When the compressed message is 0x06, 0x07, or 0x08, the code attempts to access States a, b, and e, respectively. Decompression failure should occur in this case because the relevant states are no longer available.

The cost in UDVM cycles for each compressed message is given below (except for messages 0x06, 0x07, and 0x08 where decompression failure should to occur):

<table>
<thead>
<tr>
<th>Compressed message</th>
<th>Cost in UDVM cycles</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x00 0x01 0x02 0x03 0x04 0x05 0x06 0x07 0x08</td>
<td>1809 1809 1809 1993 1994 1804 N/A N/A N/A</td>
</tr>
</tbody>
</table>
4.4. Accessing RFC 3485 State

This section gives assembly code to test accessing SIP-SDP static dictionary state [3]. The code first accesses the state and then outputs the result.

```
at (32)

:input     pad (1)
:input2    pad (1)
:input3    pad (1)
```
STATE-ACCESS (sip_dictionary, 20, 0xcfe, 1, input, 0)
STATE-ACCESS (sip_dictionary, 6, 0xcff, 1, input2, 0)
STATE-ACCESS (sip_dictionary, 12, 0xd00, 1, input3, 0)

OUTPUT (input, 3)

END-MESSAGE (0, 0, 0, 0, 0, 0, 0)

:sip_dictionary
byte (0xfb, 0xe5, 0x07, 0xdf, 0xe5, 0xe6)
byte (0xaa, 0x5a, 0xf2, 0xab, 0xb9, 0x14)
byte (0xce, 0xaa, 0x05, 0xf9, 0x9c, 0xe6)
byte (0x1b, 0xa5)

The output of the code is 0x5349 50, and the cost is 11 UDVM cycles.

4.5. Bytecode State Creation

This section gives assembly code to test storing bytecode using END-MESSAGE and later loading the bytecode using a partial state identifier within the SigComp header. The assembly code is designed to test the following cases:

1. The bytes to be saved are changed after the state create request has been made.
2. The uploaded bytecode is modified before execution.
3. The bytecode is loaded using the partial state identifier and is modified before execution.
4. The bytecode is loaded to an address lower than 128, using the partial state identifier.
5. The bytecode is loaded using the partial state identifier. Part of the loaded memory is reserved area, which is overwritten after loading the bytecode.
6. The loading of the bytecode fails because the partial state identifier is too short.

First message: mnemonic code annotated above

0xf804 6112 a0be 081e 2008 1e21 060a 0e23 be03 12a0 be08 a050 2008
0xa050 a053 140a 2008 a050 a053 0c0a 1606 004f 4b31 1c01 a0b3 fc22
0xa0a8 0323 0000 0da0 a8a0 a8b6 a04f 4b32 22a0 5003 2302

Second message: access and run last state saved by previous message - 'ok1', INPUT-BYTES, OUTPUT, END-MESSAGE.

0xf905 b88c e72c 9103

Third message: access and run state from save_area2 with 12 bytes of state identifier - 'ok2', INPUT-BYTES, OUTPUT, END-MESSAGE.

0xfb24 63c5 ff5c f8c7 6df6 a289 ff

Fourth message: access and run state from save_area1. The state is 'ok2', INPUT-BYTES, OUTPUT, END-MESSAGE but the first two bytes should be overwritten when initialising UDVM memory.
Fifth message: attempt to access state from save_area2 with fewer than 20 bytes of state identifier.

5. Security Considerations

This document describes torture tests for the SigComp protocol RFC 3320 [2]. Consequently, the security considerations for this document match those of SigComp.

In addition, the torture tests include tests for a significant number of "boundary and error cases" for execution of the UDVM bytecode. Boundary and error problems are common vectors for security attacks, so ensuring that a UDVM implementation executes this set of torture tests correctly should contribute to the security of the implementation.

6. Acknowledgements

Thanks to Richard Price and Pekka Pessi for test contributions and to Pekka Pessi and Cristian Constantin, who served as committed working group document reviewers.

7. Normative References

Appendix A. UDVM Bytecode for the Torture Tests

The following sections list the raw UDVM bytecode generated for each test. The bytecode is presented in the form of a complete SigComp message, including the appropriate header. It is followed by input messages, the output they produce, and where the decompression succeeds the number of cycles used.

In some cases, the test is designed to be run several times with different compressed messages appended to the code. In the cases where multiple whole messages are used for a test, e.g., Appendix A.2.3, these are supplied. In the case where decompression failure occurs, the high-level reason for it is given as a reason code defined in NACK [4].

Note that the different assemblers can output different bytecode for the same piece of assembly code, so a valid assembler can produce results different from those presented below. However, the following bytecode should always generate the same results on any UDVM.

0x0423 0000 0000 0000 0074 6573 74
```

Input: None
Input: 0x00
Output: 0x7465 7374
Cycles: 26

Input: 0x01
Output: 0x7465 7374
Cycles: 15

Input: 0x02
DECOMPRESSION-FAILURE STATE_NOT_FOUND

Input: 0x03
DECOMPRESSION-FAILURE STATE_NOT_FOUND (len < min_acc_len)

Input: 0x04
DECOMPRESSION-FAILURE STATE_TOO_SHORT

A.2. Dispatcher Tests

A.2.1. Useful Values

```
0xf805 f10e 8620 0ea0 4221 1c01 a047 f817 4263 f306 f317 4300 ed06
0x0c17 4400 e73f e717 44a3 c0e1 07e1 1c01 a047 9fda 0623 4007 2301
0x1220 0163 1c01 a049 9fca 0ea0 4443 0622 0308 2208 0622 a3e8 0822
0x4106 2264 0722 a358 1220 6220 2300 00a3 c086 8706
```

Input: 1 byte of SigComp version
Output: None
Cycles: 968

0xf93a db1d 3d20 aa

Input: 1 byte of SigComp version then 0x0000
Output: None
Cycles: cycles_per_bit * 1080

Input: 1 byte of SigComp version then 0x0001
DECOMPRESSION-FAILURE CYCLES_EXHAUSTED

Input: 1 byte of SigComp version then 0x0100
DECOMPRESSION-FAILURE SEGFAULT
A.2.2. Cycles Checking

0xf801 a10f 8604 2029 0022 12a0 4402 6014 02a0 6423 22a0 4402 0622 0x0116 ef

Input: None
DECOMPRESSION-FAILURE CYCLES_EXHAUSTED

A.2.3. Message-based Transport

0xf8

Input: None
DECOMPRESSION-FAILURE MESSAGE_TOO_SHORT

0xf800

Input: None
DECOMPRESSION-FAILURE MESSAGE_TOO_SHORT

0xf800 e106 0011 2200 0223 0000 0000 0000 01

Input: None
Output: decompression_memory_size
Cycles: 5

0xf800 f106 0011 2200 0223 0000 0000 0000 01

Input: None
DECOMPRESSION-FAILURE MESSAGE_TOO_SHORT

0xf800 e006 0011 2200 0223 0000 0000 0000 01

Input: None
DECOMPRESSION-FAILURE INVALID_CODE_LOCATION

0xf800 ee06 0011 2200 0223 0000 0000 0000 01

Input: None
Output: decompression_memory_size
Cycles: 5

A.2.4. Stream-based Transport

0xffff f801 7108 0002 2200 0222 a092 0523 0000 0000 0000 00ff 00ff 0x01 f801 7e08 0002 2200 0222 a3d2 0523 0000 0000 0x0000 00ff 04ff 00ff 00ff 00ff ff
The above stream contains two messages:

Output: decompression_memory_size
Cycles: 11

Output: decompression_memory_size
Cycles: 11

0xf8ff ff

Input: None

DECOMPRESSION-FAILURE  MESSAGE_TOO_SHORT

0x800 ffff

Input: None

DECOMPRESSION-FAILURE  MESSAGE_TOO_SHORT

0xf801 8108 0002 2200 0222 a092 0523 ffff 0000 0000 0000 00ff 00ff

0x03ff ffff

Input: None

DECOMPRESSION-FAILURE  MESSAGE_TOO_SHORT

0xf801 7008 0002 2200 0222 a092 0523 ffff 0000 0000 0000 00ff 04ff

0xfff ffff

Input: None

DECOMPRESSION-FAILURE  INVALID_CODE_LOCATION

A.2.5. Input Past the End of a Message

0xf803 210e 86a0 460e a042 a04d 1d09 a046 0a1c 07a0 4606 001d 07a0
0x46ff 1c02 a046 fa22 a046 021d 10a0 4606 001d 08a0 46ff 22a0 4701
0x23

Input: 0xfffa 0068 6921
Output: 0x6869 21
Cycles: 23

Input: 0xfffa 0068 69

DECOMPRESSION-FAILURE  USER_REQUESTED  (not enough bits)
A.3. State Handler Tests

A.3.1. SigComp Feedback Mechanism

Input: 0x00
Output: None
Cycles: 52

Input: 0x01
Output: None
Cycles: 179

A.3.2. State Memory Management

Input: 0x00
Output: None
Cycles: 811

Input: 0x01
Output: None
Cycles: 2603
A.3.3. Multiple Compartments

Input: 0x00
Output: None
Cycles: 1809

Input: 0x01
Output: None
Cycles: 1809
Input: 0x02
Output: None
Cycles: 1809

Input: 0x03
Output: None
Cycles: 1993

Input: 0x04
Output: None
Cycles: 1994

Input: 0x05
Output: None
Cycles: 1804

Input: 0x06
DECOMPRESSION-FAILURE STATE_NOT_FOUND

Input: 0x07
DECOMPRESSION-FAILURE STATE_NOT_FOUND

Input: 0x08
DECOMPRESSION-FAILURE STATE_NOT_FOUND

A.3.4. Accessing RFC 3485 State

0xf803 a11f a0a6 14ac fe01 2000 1fa0 a606 acff 0121 001f a0a6 0cad
0x0001 2200 2220 0323 0000 0000 00fb e507 dfe5 e6aa 5af2 abb9
0x14ce aa05 f99c e61b a5

Input: None
Output: 0x5349 50
Cycles: 11

A.3.5. Bytecode State Creation

0xf804 6112 a0be 081e 2008 1e21 060a 0e23 be03 12a0 be08 a050 2008
