Definitions of Managed Objects
for the DS1, J1, E1, DS2, and E2 Interface Types

Status of This Memo

This document specifies an Internet standards track protocol for the Internet community, and requests discussion and suggestions for improvements. Please refer to the current edition of the "Internet Official Protocol Standards" (STD 1) for the standardization state and status of this protocol. Distribution of this memo is unlimited.

Abstract

This memo defines a portion of the Management Information Base (MIB) for use with network management protocols in the Internet community. In particular, it describes objects used for managing DS1, J1, E1, DS2, and E2 interfaces. This document is a companion to the documents that define managed objects for the DS0, DS3/E3, and Synchronous Optical Network/Synchronous Digital Hierarchy (SONET/SDH) Interface Types.

This document obsoletes RFC 3895.
1. The Internet-Standard Management Framework

For a detailed overview of the documents that describe the current Internet-Standard Management Framework, please refer to section 7 of RFC 3410 [RFC3410].

Managed objects are accessed via a virtual information store, termed the Management Information Base or MIB. MIB objects are generally accessed through the Simple Network Management Protocol (SNMP). Objects in the MIB are defined using the mechanisms defined in the Structure of Management Information (SMI). This memo specifies a MIB module that is compliant to the SMIV2, which is described in STD 58, RFC 2578 [RFC2578], STD 58, RFC 2579 [RFC2579] and STD 58, RFC 2580 [RFC2580].
2. Conventions Used in This Document

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC 2119 [RFC2119].

3. Overview

These objects are used when the particular media being used to realize an interface is a DS1/J1/E1/DS2/E2 interface. At present, this applies to the following value of the ifType variable in the Internet-standard MIB:

ds1 (18)

The definitions contained herein are based on the AT&T T-1 Superframe (a.k.a. D4) [ANSI-T1.107] and Extended Superframe (ESF) formats [AT&T-UM-305], [AT&T-TR-54016], the latter of which conforms to ANSI specifications [ANSI-T1.403], and the CCITT Recommendations [CCITT-G.703], [ITU-T-G.704], referred to as E1 for the rest of this memo. J1 refers to the definition presented in [JT-G704], [JT-G706], and [JT-I431].

The various DS1, J1, and E1 line disciplines are similar enough that separate MIBs are unwarranted, although there are some differences. For example, Loss of Frame is defined more rigorously in the ESF specification than in the D4 specification, or Yellow Alarm generation and detection are a bit different between T1 and J1 but in both examples, there is definition in both related lines. Therefore, interface types e1(19) and g703at2mb(67) have been obsoleted and there is also no need for special type for J1.

Where it is necessary to distinguish between the flavors of E1 with and without Cyclic Redundancy Check (CRC), E1-CRC denotes the "with CRC" form (G.704 Table 5B) and E1-noCRC denotes the "without CRC" form (G.704 Table 5A).
3.1. Use of ifTable for DS1 Layer

Only the ifGeneralInformationGroup needs to be supported.

3.2. Usage Guidelines

3.2.1. Usage of ifStackTable for Routers and DSUs

The object dsxlIfIndex has been deprecated. This object previously allowed a very special proxy situation to exist for routers and Channel Service Units (CSUs). This section now describes how to use the ifStackTable to represent this relationship.

The paragraphs discussing dsxlIfIndex and dsxlLineIndex have been preserved in Appendix A for informational purposes.

The ifStackTable is used in the proxy case to represent the association between pairs of interfaces, i.e., this T1 is attached to that T1. This use is consistent with the use of the ifStackTable to show the association between various sub-layers of an interface. In both cases, entire PDUs are exchanged between the interface pairs -- in the case of a T1, entire T1 frames are exchanged; in the case of PPP and High-Level Data Link Control (HDLC), entire HDLC frames are exchanged. This usage is not meant to suggest the use of the ifStackTable to represent Time Division Multiplexing (TDM) connections in general.

External and Internal interface scenario: the SNMP agent resides on a host external from the device supporting DS1 interfaces (e.g., a router). The agent represents both the host and the DS1 device.
Example:

A shelf full of CSUs connected to a router. An SNMP agent residing on the router proxies for itself and the CSU. The router has also an Ethernet interface:

```
+-----+               +---------------------+          +-----+
|     |               |                     |          |     |
|     |               |                     |          |     |
| E    |  1.544 MBPS | Line#A | DS1 Link          | E    |
| t    | R              | - - - - - - - - - - +----> | t    |
| h    | 1.544 MBPS | Line#B | DS1 Link          | h    |
| e    | O              | - - - - - - - - - - +----> | e    |
| r    | 1.544 MBPS | CSU Shelf |                     | r    |
| n    | U              | - - - - - - - - - - +----> | n    |
| e    | T              | - - - - - - - - - - +----> | e    |
| t    | 1.544 MBPS | Line#C | DS1 Link          | t    |
| n    | U              | - - - - - - - - - - +----> | n    |
| e    | T              | - - - - - - - - - - +----> | e    |
| r    | 1.544 MBPS | Line#D | DS1 Link          | r    |
| n    | U              | - - - - - - - - - - +----> | n    |
| e    | T              | - - - - - - - - - - +----> | e    |
```

The assignment of the index values could, for example, be as follows:

<table>
<thead>
<tr>
<th>ifIndex</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Ethernet</td>
</tr>
<tr>
<td>2</td>
<td>Line#A Router</td>
</tr>
<tr>
<td>3</td>
<td>Line#B Router</td>
</tr>
<tr>
<td>4</td>
<td>Line#C Router</td>
</tr>
<tr>
<td>5</td>
<td>Line#D Router</td>
</tr>
<tr>
<td>6</td>
<td>Line#A CSU Router</td>
</tr>
<tr>
<td>7</td>
<td>Line#B CSU Router</td>
</tr>
<tr>
<td>8</td>
<td>Line#C CSU Router</td>
</tr>
<tr>
<td>9</td>
<td>Line#D CSU Router</td>
</tr>
<tr>
<td>10</td>
<td>Line#A CSU Network</td>
</tr>
<tr>
<td>11</td>
<td>Line#B CSU Network</td>
</tr>
<tr>
<td>12</td>
<td>Line#C CSU Network</td>
</tr>
<tr>
<td>13</td>
<td>Line#D CSU Network</td>
</tr>
</tbody>
</table>

The ifStackTable is then used to show the relationships between the various DS1 interfaces.
ifStackTable Entries

<table>
<thead>
<tr>
<th>HigherLayer</th>
<th>LowerLayer</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>6</td>
</tr>
<tr>
<td>3</td>
<td>7</td>
</tr>
<tr>
<td>4</td>
<td>8</td>
</tr>
<tr>
<td>5</td>
<td>9</td>
</tr>
<tr>
<td>6</td>
<td>10</td>
</tr>
<tr>
<td>7</td>
<td>11</td>
</tr>
<tr>
<td>8</td>
<td>12</td>
</tr>
<tr>
<td>9</td>
<td>13</td>
</tr>
</tbody>
</table>

If the CSU shelf is managed by itself by a local SNMP agent, the situation would be identical, except the Ethernet and the four router interfaces are deleted. Interfaces would also be numbered from 1 to 8.

</tbody>
</table>

3.2.2. Usage of ifStackTable for DS1/J1/E1 on DS2/E2

An example is given of how DS1/J1/E1 interfaces are stacked on DS2/E2 interfaces. It is not necessary nor is it always desirable to represent DS2 interfaces. If this is required, the following stacking should be used. All ifTypes are ds1. The DS2 is determined by examining ifSpeed or dsxlLineType.
ifIndex  Description
1        DS1 #1
2        DS1 #2
3        DS1 #3
4        DS1 #4
5        DS2

ifStackTable Entries

HigherLayer  LowerLayer
1            5
2            5
3            5
4            5

3.2.3. Usage of Channelization for DS3, DS1, DS0

An example is given here to explain the channelization objects in the DS3, DS1, and DS0 MIBs to help the implementer use the objects correctly. Treatment of E3 and E1 would be similar, with the number of DS0s being different depending on the framing of the E1.

Assume that a DS3 (with ifIndex 1) is channelized into DS1s (without DS2s). The object dsx3Channelization is set to enabledDs1. There will be 28 DS1s in the ifTable. Assume the entries in the ifTable for the DS1s are created in channel order and the ifIndex values are 2 through 29. In the DS1 MIB, there will be an entry in the dsx1ChanMappingTable for each DS1. The entries will be as follows:

dsx1ChanMappingTable Entries

<table>
<thead>
<tr>
<th>ifIndex</th>
<th>dsx1Ds1ChannelNumber</th>
<th>dsx1ChanMappedIfIndex</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>......</td>
<td></td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>28</td>
<td>29</td>
</tr>
</tbody>
</table>

In addition, the DS1s are channelized into DS0s. The object dsx1Channelization is set to enabledDS0 for each DS1. When this object is set to this value, 24 DS0s are created by the agent. There will be 24 DS0s in the ifTable for each DS1. If the dsx1Channelization is set to disabled, the 24 DS0s are destroyed.

Assume the entries in the ifTable are created in channel order and the ifIndex values for the DS0s in the first DS1 are 30 through 53. In the DS0 MIB, there will be an entry in the dsx0ChanMappingTable for each DS0. The entries will be as follows:
dsx0ChanMappingTable Entries

<table>
<thead>
<tr>
<th>ifIndex</th>
<th>dsx0Ds0ChannelNumber</th>
<th>dsx0ChanMappedIfIndex</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>1</td>
<td>30</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>31</td>
</tr>
<tr>
<td>......</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>24</td>
<td>53</td>
</tr>
</tbody>
</table>

3.2.4. Usage of Channelization for DS3, DS2, DS1

An example is given here to explain the channelization objects in the DS3 and DS1 MIBs to help the implementer use the objects correctly.

Assume that a DS3 (with ifIndex 1) is channelized into DS2s. The object dsx3Channelization [RFC3896] is set to enabledDs2. There will be 7 DS2s (ifType of DS1) in the ifTable. Assume the entries in the ifTable for the DS2s are created in channel order and the ifIndex values are 2 through 8. In the DS1 MIB, there will be an entry in the dsx1ChanMappingTable for each DS2. The entries will be as follows:

dsx1ChanMappingTable Entries

<table>
<thead>
<tr>
<th>ifIndex</th>
<th>dsx1Ds1ChannelNumber</th>
<th>dsx1ChanMappedIfIndex</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>......</td>
<td></td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>7</td>
<td>8</td>
</tr>
</tbody>
</table>

In addition, the DS2s are channelized into DS1s. The object dsx1Channelization is set to enabledDS1 for each DS2. There will be 4 DS1s in the ifTable for each DS2. Assume the entries in the ifTable are created in channel order and the ifIndex values for the DS1s in the first DS2 are 9 through 12, then 13 through 16 for the second DS2, and so on. In the DS1 MIB, there will be an entry in the dsx1ChanMappingTable for each DS1. The entries will be as follows:

dsx1ChanMappingTable Entries

<table>
<thead>
<tr>
<th>ifIndex</th>
<th>dsx1Ds1ChannelNumber</th>
<th>dsx1ChanMappedIfIndex</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>1</td>
<td>9</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>10</td>
</tr>
<tr>
<td>2</td>
<td>3</td>
<td>11</td>
</tr>
<tr>
<td>2</td>
<td>4</td>
<td>12</td>
</tr>
<tr>
<td>3</td>
<td>1</td>
<td>13</td>
</tr>
<tr>
<td>3</td>
<td>2</td>
<td>14</td>
</tr>
<tr>
<td>......</td>
<td></td>
<td></td>
</tr>
<tr>
<td>8</td>
<td>4</td>
<td>36</td>
</tr>
</tbody>
</table>
3.2.5. Usage of Loopbacks

This section discusses the behavior of objects related to loopbacks.

The object dsxlLoopbackConfig represents the desired state of loopbacks on this interface. Using this object, a manager can request

- LineLoopback
- PayloadLoopback (if ESF framing)
- InwardLoopback
- DualLoopback (Line + Inward)
- NoLoopback

The remote end can also request loopbacks either through the Facility Data Link (FDL) channel if ESF or inband if D4. The loopbacks that can be requested this way are

- LineLoopback
- PayloadLoopback (if ESF framing)
- NoLoopback

To model the current state of loopbacks on a DS1 interface, the object dsxlLoopbackStatus defines which loopback is currently applied to an interface. This object, which is a bitmap, will have bits turned on that reflect the currently active loopbacks on the interface as well as the source of those loopbacks.

The following restrictions/rules apply to loopbacks:

- The far end cannot undo loopbacks set by a manager.
- A manager can undo loopbacks set by the far end.
- Both a line loopback and an inward loopback can be set at the same time. Only these two loopbacks can co-exist and either one may be set by the manager or the far end. A LineLoopback request from the far end is incremental to an existing Inward loopback established by a manager. When a NoLoopback is received from the far end in this case, the InwardLoopback remains in place.

3.3. Objectives of This MIB Module

There are numerous things that could be included in a MIB for DS1 signals: the management of multiplexers, CSUs, Data Service Units (DSUs), and the like. The intent of this document is to facilitate the common management of all devices with DS1, J1, E1, DS2, or E2 interfaces. As such, a design decision was made up front to very
closely align the MIB with the set of objects that can generally be read from these types of devices that are currently deployed.

J2 interfaces are not supported by this MIB.

3.4. DS1 Terminology

The terminology used in this document to describe error conditions on a DS1 interface as monitored by a DS1 device are based on the latest ANSI T1.231 standard [ANSI-T1.231]. If the definition in this document does not match the definition in the ANSI T1.231 document, the implementer should follow the definition described in this document.

3.4.1. Error Events

Bipolar Violation (BPV) Error Event
A BPV error event for an AMI-coded (AMI stands for Alternate Mark Inversion) signal is the occurrence of a pulse of the same polarity as the previous pulse (see T1.231, Section 4.2.1.1.1). A BPV error event for a B8ZS- or HDB3-coded signal is the occurrence of a pulse of the same polarity as the previous pulse without being a part of the zero substitution code.

Excessive Zeroes (EXZ) Error Event
An Excessive Zeroes error event for an AMI-coded signal is the occurrence of more than fifteen contiguous zeroes (see T1.231, Section 4.2.1.1.2). For a B8ZS-coded signal, the defect occurs when more than seven contiguous zeroes are detected.

Line Coding Violation (LCV) Error Event
A Line Coding Violation (LCV) is the occurrence of either a Bipolar Violation (BPV) or Excessive Zeroes (EXZ) error event. (Also known as CV-L; see T1.231, Section 4.6.1.1.)

Path Coding Violation (PCV) Error Event
A Path Coding Violation error event is a frame synchronization bit error in the D4 and E1-noCRC formats, or a CRC or frame synch. bit error in the ESF and E1-CRC formats. (Also known as CV-P; see T1.231, Section 4.6.2.1.)

Controlled Slip (CS) Error Event
A Controlled Slip is the replication or deletion of the payload bits of a DS1 frame (see T1.231, Section 4.2.1.2.3). A Controlled Slip may be performed when there is a difference between the timing of a synchronous receiving terminal and the received signal. A Controlled Slip does not cause an Out of Frame defect.
3.4.2. Performance Defects

Out of Frame (OOF) Defect

An OOF defect is the occurrence of a particular density of Framing Error events (see T1.231, Section 4.2.2.2.1).

For DS1 links, an Out of Frame defect is declared when the receiver detects two or more framing errors within a 3-msec period for ESF signals and 0.75 msec for D4 signals, or two or more errors out of five or fewer consecutive framing bits.

For E1 links, an Out of Frame defect is declared when three consecutive frame alignment signals have been received with an error (see G.706, Section 4.1 [CCITT-G.706]).

For DS2 links, an Out of Frame defect is declared when seven or more consecutive errored framing patterns (four multiframe) are received. The OOF is cleared when three or more consecutive correct framing patterns are received.

Once an Out Of Frame Defect is declared, the framer starts searching for a correct framing pattern. The Out of Frame defect ends when the signal is in-frame.

In-frame occurs when there are fewer than two frame bit errors within a 3-msec period for ESF signals and 0.75 msec for D4 signals.

For E1 links, in-frame occurs when a) in frame N the frame alignment signal is correct and b) in frame N+1 the frame alignment signal is absent (i.e., bit 2 in TS0 is a one) and c) in frame N+2 the frame alignment signal is present and correct (see G.704, Section 4.1).

Alarm Indication Signal (AIS) Defect

For D4 and ESF links, the ‘all ones’ condition is detected at a DS1 line interface upon observing an unframed signal with a one’s density of at least 99.9% present for a time equal to or greater than T, where 3 ms <= T <= 75 ms. The AIS is terminated upon observing a signal not meeting the one’s density or the unframed signal criteria for a period equal to or greater than T (see G.775, Section 5.4).

For E1 links, the ‘all-ones’ condition is detected at the line interface as a string of 512 bits containing fewer than three zero bits (see 0.162 [ITU-T-0.162], Section 3.3.2).
For DS2 links, the DS2 AIS shall be sent from the NT1 to the user to indicate a loss of the 6,312-kbps frame capability on the network side. The DS2 AIS is defined as a bit array of 6,312 kbps in which all binary bits are set to ‘1’.

The DS2 AIS detection and removal shall be implemented according to ITU-T Draft Recommendation G.775 [ITU-T-G.775] Section 5.5:

- a DS2 AIS defect is detected when the incoming signal has two or less zeroes in a sequence of 3156 bits (0.5 ms).
- a DS2 AIS defect is cleared when the incoming signal has three or more zeroes in a sequence of 3156 bits (0.5 ms).

3.4.3. Performance Parameters

All performance parameters are accumulated in 15-minute intervals, and up to 96 intervals (24 hours’ worth) are kept by an agent. Fewer than 96 intervals of data will be available if the agent has been restarted within the last 24 hours. In addition, there is a rolling 24-hour total of each performance parameter. Performance parameters continue to be collected when the interface is down.

There is no requirement for an agent to ensure a fixed relationship between the start of a 15-minute interval and any wall clock; however, some agents may align the 15-minute intervals with quarter hours.

Performance parameters are of types PerfCurrentCount, PerfIntervalCount, and PerfTotalCount. These textual conventions are all Gauge32, and they are used because it is possible for these objects to decrease. Objects may decrease when Unavailable Seconds occur across a 15-minute interval boundary. See Unavailable Second discussion later in this section.

Line Errored Second (LES)
A Line Errored Second is a second in which one or more Line Coding Violation error events were detected. (Also known as ES-L; see T1.231, Section 4.6.1.2.)

Controlled Slip Second (CSS)
A Controlled Slip Second is a one-second interval containing one or more controlled slips (see T1.231, Section 4.6.2.9). This is not incremented during an Unavailable Second.
Errored Second (ES)
For ESF and E1-CRC links, an Errored Second is a second with one or more Path Coding Violations OR one or more Out of Frame defects OR one or more Controlled Slip events OR a detected AIS defect. (See T1.231, Section 4.6.2.2 and G.826 [ITU-T-G.826], Section B.1).

For D4 and E1-noCRC links, the presence of Bipolar Violations also triggers an Errored Second.

This is not incremented during an Unavailable Second.

Bursty Errored Second (BES)
A Bursty Errored Second (also known as Errored Second type B in T1.231, Section 4.6.2.4) is a second with fewer than 320 and more than 1 Path Coding Violation error events, no Severely Errored Frame defects, and no detected incoming AIS defects. Controlled Slips are not included in this parameter.

This is not incremented during an Unavailable Second. It applies to ESF signals only.

Severely Errored Second (SES)
A Severely Errored Second for ESF signals is a second with 320 or more Path Coding Violation error events OR one or more Out of Frame defects OR a detected AIS defect (see T1.231, Section 4.6.2.5).

For E1-CRC signals, a Severely Errored Second is a second with 832 or more Path Coding Violation error events OR one or more Out of Frame defects.

For E1-noCRC signals, a Severely Errored Second is 2048 LCVs or more.

For D4 signals, a Severely Errored Second is a count of one-second intervals with Framing Error events, or an OOF defect, or 1544 LCVs or more.

Controlled Slips are not included in this parameter.

This is not incremented during an Unavailable Second.

Severely Errored Framing Second (SEFS)
An Severely Errored Framing Second is a second with one or more Out of Frame defects OR a detected AIS defect. (Also known as SAS-P (SEF/AIS second); see T1.231, Section 4.6.2.6.)
Degraded Minutes
A Degraded Minute is one in which the estimated error rate exceeds 1E-6 but does not exceed 1E-3 (see G.821 [CCITT-G.821]).

Degraded Minutes are determined by collecting all of the Available Seconds, removing any Severely Errored Seconds, grouping the result in 60-second long groups, and counting a 60-second long group (a.k.a. minute) as degraded if the cumulative errors during the seconds present in the group exceed 1E-6. Available seconds are merely those seconds that are not Unavailable as described below.

Unavailable Second (UAS)
Unavailable Seconds (UASs) are calculated by counting the number of seconds that the interface is unavailable. The DS1 interface is said to be unavailable from the onset of 10 contiguous SESs, or the onset of the condition leading to a failure (see Failure States). If the condition leading to the failure was immediately preceded by one or more contiguous SESs, then the DS1 interface unavailability starts from the onset of these SESs. Once unavailable, and if no failure is present, the DS1 interface becomes available at the onset of 10 contiguous seconds with no SESs. Once unavailable, and if a failure is present, the DS1 interface becomes available at the onset of 10 contiguous seconds with no SESs, if the failure clearing time is less than or equal to 10 seconds. If the failure clearing time is more than 10 seconds, the DS1 interface becomes available at the onset of 10 contiguous seconds with no SESs, or the onset period leading to the successful clearing condition, whichever occurs later. With respect to the DS1 error counts, all counters are incremented while the DS1 interface is deemed available. While the interface is deemed unavailable, the only count that is incremented is UASs.

Note that this definition implies that the agent cannot determine until after a 10-second interval has passed whether a given one-second interval belongs to available or unavailable time. If the agent chooses to update the various performance statistics in real time, then it must be prepared to retroactively reduce the ES, BES, SES, and SEFS counts by 10 and increase the UAS count by 10 when it determines that available time has been entered. It must also be prepared to adjust the PCV count and the DM count as necessary since these parameters are not accumulated during unavailable time. It must be similarly prepared to retroactively decrease the UAS count by 10 and increase the ES, BES, and DM counts as necessary upon entering available time. A special case exists when the 10-second period leading to available or unavailable time crosses a 900-second statistics window boundary, as the foregoing description implies that the ES, BES, SES, SEFS,
DM, and UAS counts the PREVIOUS interval must be adjusted. In
this case, successive GETs of the affected dsx1IntervalSESs and
dsx1IntervalUASs objects will return differing values if the first
GET occurs during the first few seconds of the window.

The agent may instead choose to delay updates to the various
statistics by 10 seconds in order to avoid retroactive adjustments
to the counters. A way to do this is sketched in Appendix B.

In any case, a linkDown trap shall be sent only after the agent has
determined for certain that the unavailable state has been entered,
but the time on the trap will be that of the first UAS (i.e., 10
seconds earlier). A linkUp trap shall be handled similarly.

According to ANSI T1.231, unavailable time begins at the onset of 10
contiguous severely errored seconds -- that is, unavailable time
starts with the first of the 10 contiguous SESs. Also, while an
interface is deemed unavailable all counters for that interface are
frozen except for the UAS count. It follows that an implementation
that strictly complies with this standard must not increment any
counters other than the UAS count -- even temporarily -- as a result
of anything that happens during those 10 seconds. Since changes in
the signal state lag the data to which they apply by 10 seconds, an
ANSI-compliant implementation must pass the one-second statistics
through a 10-second delay line prior to updating any counters. That
can be done by performing the following steps at the end of each
one-second interval.

i) Read near/far end CV counter and alarm status flags from the
hardware.

ii) Accumulate the CV counts for the preceding second and compare
them to the ES and SES threshold for the layer in question.
Update the signal state and shift the one-second CV counts and
ES/SES flags into the 10-element delay line. Note that far-end
one-second statistics are to be flagged as "absent" during any
second in which there is an incoming defect at the layer in
question or at any lower layer.

iii) Update the current interval statistics using the signal state
from the previous update cycle and the one-second CV counts and
ES/SES flags shifted out of the 10-element delay line.

This approach is further described in Appendix B.
3.4.4. Failure States

The following failure states are received, or detected failures, that are reported in the dsxlLineStatus object. When a DS1 interface would, if ever, produce the conditions leading to the failure state is described in the appropriate specification.

Far End Alarm Failure

The Far End Alarm failure is also known as "Yellow Alarm" in the DS1 and J1 cases, "Distant Alarm" in the E1 case, and "Remote Alarm" in the DS2 case.

For D4 links, the Far End Alarm failure is declared when bit 6 of all channels has been zero for at least 335 ms and is cleared when bit 6 of at least one channel is non-zero for a period T, where T is usually less than one second and always less than five seconds. The Far End Alarm failure is not declared for D4 links when a Loss of Signal is detected. In J1 the 12th F-bit is set to 1.

For ESF links, the Far End Alarm failure is declared if the Yellow Alarm signal pattern occurs in at least seven out of ten contiguous 16-bit pattern intervals and is cleared if the Yellow Alarm signal pattern does not occur in ten contiguous 16-bit signal pattern intervals. For DS1 the patterns is FF00 and for J1 the pattern is FFFF.

For E1 links, the Far End Alarm failure is declared when bit 3 of time-slot zero is received set to one on two consecutive occasions. The Far End Alarm failure is cleared when bit 3 of time-slot zero is received set to zero.

For DS2 links, if a loss of frame alignment (LOF or LOS) and/or DS2 AIS condition is detected, the RAI signal shall be generated and transmitted to the remote side.

The Remote Alarm Indication (RAI) signal is defined on m-bits as a repetition of the 16-bit sequence consisting of eight binary '1s' and eight binary '0s' in m-bits(1111111000000000). When the RAI signal is not sent (in normal operation), the HDLC flag pattern (01111110) in the m-bit is sent.

The RAI failure is detected when 16 or more consecutive RAI-patterns (1111111000000000) are received. The RAI failure is cleared when 4 or more consecutive incorrect-RAI-patterns are received.
Alarm Indication Signal (AIS) Failure

The Alarm Indication Signal failure is declared when an AIS defect is detected at the input and the AIS defect still exists after the Loss of Frame failure (which is caused by the unframed nature of the ‘all-ones’ signal) is declared. The AIS failure is cleared when the Loss of Frame failure is cleared. (See T1.231, Section 4.3.1.2.2).

An AIS defect at a 6312-kbit/s (G.704) interface is detected when the incoming signal has two or less zeroes in a sequence of 3156 bits (0.5ms).

The AIS signal defect is cleared when the incoming signal has three (3) or more zeroes in a sequence of 3156 bits (0.5ms).

Loss Of Frame (LOF) Failure

For DS1 links, the Loss of Frame failure is declared when an OOF or LOS defect has persisted for T seconds, where 2 <= T <= 10. The Loss of Frame failure is cleared when there have been no OOF or LOS defects during a period T where 0 <= T <= 20. Many systems will perform ”hit integration” within the period T before declaring or clearing the failure; e.g., see TR 62411 [AT&T-TR-62411].

For E1 links, the Loss of Frame failure is declared when an OOF defect is detected.

Loss Of Signal (LOS) Failure

For DS1, the Loss of Signal failure is declared upon observing 175 +/- 75 contiguous pulse positions with no pulses of either positive or negative polarity. The LOS failure is cleared upon observing an average pulse density of at least 12.5% over a period of 175 +/- 75 contiguous pulse positions starting with the receipt of a pulse.

For E1 links, the Loss of Signal failure is declared when greater than 10 consecutive zeroes are detected (see O.162, Section 3.4.4).

A LOS defect at 6312kbit/s interfaces is detected when the incoming signal has "no transitions", i.e., when the signal level is less than or equal to a signal level of 35dB below nominal, for N consecutive pulse intervals, where 10 <= N <= 255.

The LOS defect is cleared when the incoming signal has "transitions", i.e., when the signal level is greater than or equal to a signal level of 9dB below nominal, for N consecutive pulse intervals, where 10 <= N <= 255.
A signal with "transitions" corresponds to a G.703-compliant signal.

Loopback Pseudo-Failure
The Loopback Pseudo-Failure is declared when the near-end equipment has placed a loopback (of any kind) on the DS1. This allows a management entity to determine from one object whether the DS1 can be considered to be in service or not (from the point of view of the near-end equipment).

TS16 Alarm Indication Signal Failure
For E1 links, the TS16 Alarm Indication Signal failure is declared when time-slot 16 is received as all ones for all frames of two consecutive multiframes (see G.732, Section 4.2.6). This condition is never declared for DS1.

Loss of MultiFrame Failure
The Loss of MultiFrame failure is declared when two consecutive multiframe alignment signals (bits 4 through 7 of TS16 of frame 0) have been received with an error. The Loss of Multiframe failure is cleared when the first correct multiframe alignment signal is received. The Loss of Multiframe failure can only be declared for E1 links operating with G.732 [CCITT-G.732] framing (sometimes called "Channel Associated Signalling" mode).

Far End Loss of MultiFrame Failure
The Far End Loss of MultiFrame failure is declared when bit 2 of TS16 of frame 0 is received set to one on two consecutive occasions. The Far End Loss of MultiFrame failure is cleared when bit 2 of TS16 of frame 0 is received set to zero. The Far End Loss of MultiFrame failure can only be declared for E1 links operating in "Channel Associated Signalling" mode (see G.732).

DS2 Payload AIS Failure
The DS2 Payload AIS failure is declared when the incoming signal of the 6,312-kbps frame payload (time-slots 1 through 96) has two or less zeroes in a sequence of 3072 bits (0.5ms). The DS2 Payload AIS is cleared when the incoming signal of the 6,312-kbps frame payload has three or more zeroes in a sequence of 3072 bits (0.5 ms).

DS2 Performance Threshold Failure
DS2 Performance Threshold failure monitors equipment performance and is based on the CRC (Cyclic Redundancy Check) procedure defined in G.704.

The DS2 Performance Threshold failure is declared when the bit error ratio exceeds $10^{-4}$ (Performance Threshold), and the DS2
Performance Threshold failure is cleared when the bit error ratio decreases to less than \(10^{-6}\) .

3.4.5. Other Terms

Circuit Identifier
This is a character string specified by the circuit vendor and is useful when communicating with the vendor during the troubleshooting process (see M.1400 [ITU-T-M.1400] for additional information).

Proxy
In this document, the word proxy is meant to indicate an application that receives SNMP messages and replies to them on behalf of the devices that implement the actual DS1/E1 interfaces. The proxy may have already collected the information about the DS1/J1/E1 interfaces into its local database and may not necessarily forward the requests to the actual DS1/J1/E1 interface. It is expected in such an application that there are periods of time where the proxy is not communicating with the DS1/J1/E1 interfaces. In these instances, the proxy will not necessarily have up-to-date configuration information and will most likely have missed the collection of some statistics data. Missed statistics data collection will result in invalid data in the interval table.

DESCRIPTION

"The MIB module to describe DS1, J1, E1, DS2, and E2 interfaces objects.

Copyright (c) The IETF Trust (2007). This version of this MIB module is part of RFC 4805; see the RFC itself for full legal notices."

REVISION "200703050000Z"

DESCRIPTION

"The following changes were made:
(1) Values were added to dsx1LineType to support J1 types.
(2) The object dsx1LineImpedance was added.
(3) All DM-related objects were deprecated following their removal from ITU performance standards.

The RFC 4805 version of this MIB module."

REVISION "200409090000Z"

DESCRIPTION

"The RFC 3895 version of this MIB module.
The key changes made to this MIB module since its publication in RFC 2495 are as follows:
(1) The dsx1FracIfIndex SYNTAX matches the description range.
(2) A value was added to dsx1TransmitClockSource.
(3) Values were added to dsx1LineType.
(4) Two objects were added, dsx1LineMode and dsx1LineBuildOut, to better express transceiver mode and LineBuildOut for T1.
(5) Reference was added to Circuit Identifier object."
(6) Align the DESCRIPTION clauses of few statistic objects with the near-end definition, with the far-end definition, and with RFC 3593.
(7) Changes in Compliance Statements to include new objects.
(8) A typographical error in dsx2E2 was fixed; the new name is dsx1E2.”

REVISION "199808011830Z"

DESCRIPTION
"The RFC 2495 version of this MIB module. The key changes made to this MIB module since its publication in RFC 1406 are as follows:
(1) The Fractional table has been deprecated.
(2) This document uses SMIPv2.
(3) Usage is given for ifTable and ifXTable.
(4) Example usage of ifStackTable is included.
(5) dsx1IfIndex has been deprecated.
(6) Support for DS2 and E2 has been added.
(7) Additional lineTypes for DS2, E2, and unframed E1 were added.
(8) The definition of valid intervals has been clarified for the case where the agent proxied for other devices. In particular, the treatment of missing intervals has been clarified.
(9) An inward loopback has been added.
(10) Additional lineStatus bits have been added for Near End in Unavailable Signal State, Carrier Equipment Out of Service, DS2 Payload AIS, and DS2 Performance Threshold.
(11) A read-write line Length object has been added.
(12) Signal mode of other has been added.
(13) Added a lineStatus last change, trap and enabler.
(14) The e1(19) ifType has been obsoleted, so this MIB does not list it as a supported ifType.
(15) Textual Conventions for statistics objects have been used.
(16) A new object, dsx1LoopbackStatus, has been introduced to reflect the loopbacks established on a DS1 interface and the source to the requests. dsx1LoopbackConfig continues to be the desired loopback state while dsx1LoopbackStatus reflects the actual state.
(17) A dual loopback has been added to allow the setting of an inward loopback and a line loopback at the same time.
(18) An object indicating which channel to use within a parent object (i.e., DS3) has been added.
(19) An object has been added to indicate whether or not this DS1/E1 is channelized.
(20) Line coding type of B6ZS has been added for DS2.

MAX-ACCESS  read-write
STATUS  current
DESCRIPTION
"This variable describes the variety of Zero Code Suppression used on this interface, which in turn affects a number of its characteristics.

dsx1JBZS refers the Jammed Bit Zero Suppression, in which the AT&T specification of at least one pulse every 8-bit period is literally implemented by forcing a pulse in bit 8 of each channel. Thus, only 7 bits per channel, or 1.344 Mbps, are available for data.

dsx1B8ZS refers to the use of a specified pattern of normal bits and bipolar violations that are used to replace a sequence of 8 zero bits. ANSI Clear Channels may use dsx1ZBTSI, or Zero Byte Time Slot Interchange.

E1 links, with or without CRC, use dsx1HDB3 or dsx1AMI.

dsx1AMI refers to a mode wherein no Zero Code Suppression is present and the line encoding does
not solve the problem directly. In this application, the higher layer must provide data that meets or exceeds the pulse density requirements, such as inverting HDLC data.

dsxB6ZS refers to the user of a specified pattern of normal bits and bipolar violations that are used to replace a sequence of 6 zero bits. Used for DS2. For more information about line coding see [ANSI-T1.102]

STATUS  current
DESCRIPTION
"This variable indicates the line status of the interface. It contains loopback, failure, received alarm and transmitted alarms information.

The dsx1LineStatus is a bitmap represented as a sum; therefore, it can represent multiple failures (alarms) and a LoopbackState simultaneously.

dsx1NoAlarm must be set if and only if no other flag is set.

If the dsx1loopbackState bit is set, the loopback in effect can be determined from the dsx1loopbackConfig object. The various bit positions are as follows:

1  dsx1NoAlarm               No alarm present
2  dsx1RcvFarEndLOF          Far end LOF (a.k.a.
Yellow Alarm)
4     dsx1XmtFarEndLOF      Near end sending LOF indication
8     dsx1RcvAIS            Far end sending AIS
16    dsx1XmtAIS           Near end sending AIS
32    dsx1LossOfFrame      Near end LOF (a.k.a. Red Alarm)
64    dsx1LossOfSignal     Near end Loss of Signal
128   dsx1LoopbackState    Near end is looped
256   dsx1T16AIS           E1 TS16 AIS
512   dsx1RcvFarEndLOMF    Far end sending TS16 LOMF
1024  dsx1XmtFarEndLOMF    Near end sending TS16 LOMF
2048  dsx1RcvTestCode      Near end detects a test code
4096  dsx1OtherFailure     Any line status not defined here
8192  dsx1UnavailSigState  Near end in unavailable signal state
16384 dsx1NetEquipOOS      Carrier equipment out of service
32768 dsx1RcvPayloadAIS    DS2 payload AIS
65536 dsx1Ds2PerfThreshold DS2 performance threshold exceeded

::= { dsx1ConfigEntry 10 }

dsx1SignalMode OBJECT-TYPE
SYNTAX  INTEGER {
    none(1),
    robbedBit(2),
    bitOriented(3),
    messageOriented(4),
    other(5)
}
MAX-ACCESS  read-write
STATUS    current
DESCRIPTION
"'none' indicates that no bits are reserved for signaling on this channel. 'robbedBit' indicates that DS1 Robbed Bit Signaling is in use. 'bitOriented' indicates that E1 Channel Associated Signaling is in use. 'messageOriented' indicates that Common Channel Signaling is in use on either channel 16 of an E1 link or channel 24 of a DS1."
::= { dsx1ConfigEntry 11 }
dsx1TransmitClockSource OBJECT-TYPE
SYNTAX INTEGER {
    loopTiming(1),
    localTiming(2),
    throughTiming(3),
    adaptive (4)
}
MAX-ACCESS read-write
STATUS current
DESCRIPTION
"The source of transmit clock.

'loopTiming' indicates that the recovered receive clock is used as the transmit clock.

'localTiming' indicates that a local clock source is used or when an external clock is attached to the box containing the interface.

'throughTiming' indicates that recovered receive clock from another interface is used as the transmit clock.

'adaptive' indicates that the clock is recovered based on the data flow and not based on the physical layer"
::= { dsx1ConfigEntry 12 }

dsx1Fdl OBJECT-TYPE
SYNTAX INTEGER (1..15)
MAX-ACCESS read-write
STATUS current
DESCRIPTION
"This bitmap describes the use of the facilities data link and is the sum of the capabilities. Set any bits that are appropriate:

other(1),
dsx1AnsiT1403(2),
dsx1Att54016(4),
dsx1FdlNone(8)

'other' indicates that a protocol other than one of the following is used.

'dsx1AnsiT1403' refers to the FDL exchange recommended by ANSI."
'dsx1Att54016' refers to ESF FDL exchanges.

'dsxFdlNone' indicates that the device does not use the FDL.

::= { dsx1ConfigEntry 13 }

dsx1InvalidIntervals OBJECT-TYPE
SYNTAX INTEGER (0..96)
MAX-ACCESS read-only
STATUS current
DESCRIPTION
"The number of intervals in the range from 0 to
dsx1ValidIntervals for which no data is available.
This object will typically be zero except in cases
where the data for some intervals is not
available (e.g., in proxy situations)."
::= { dsx1ConfigEntry 14 }

dsx1LineLength OBJECT-TYPE
SYNTAX INTEGER (0..64000)
UNITS "meters"
MAX-ACCESS read-write
STATUS current
DESCRIPTION
"The length of the DS1 line in meters. This
object provides information for line build-out
circuitry. This object is only useful if the
interface has configurable line build-out
circuitry."
::= { dsx1ConfigEntry 15 }

dsx1LineStatusLastChange OBJECT-TYPE
SYNTAX TimeStamp
MAX-ACCESS read-only
STATUS current
DESCRIPTION
"The value of MIB II’s sysUpTime object at the
time this DS1 entered its current line status
state. If the current state was entered prior to
the last re-initialization of the proxy-agent,
then this object contains a zero value."
::= { dsx1ConfigEntry 16 }

dsx1LineStatusChangeTrapEnable OBJECT-TYPE
SYNTAX INTEGER {
   enabled(1),
   disabled(2)
}
MAX-ACCESS  read-write
STATUS      current
DESCRIPTION  
"Indicates whether dsx1LineStatusChange traps should be generated for this interface."
DEFVAL { disabled }
::= { dsx1ConfigEntry 17 }

dsxlLoopbackStatus OBJECT-TYPE
SYNTAX      INTEGER (1..127)
MAX-ACCESS  read-only
STATUS      current
DESCRIPTION  
"This variable represents the current state of the loopback on the DS1 interface. It contains information about loopbacks established by a manager and remotely from the far end.

The dsxlLoopbackStatus is a bitmap represented as a sum; therefore, it can represent multiple loopbacks simultaneously.

The various bit positions are as follows:
1 dsx1NoLoopback
2 dsx1NearEndPayloadLoopback
4 dsx1NearEndLineLoopback
8 dsx1NearEndOtherLoopback
16 dsx1NearEndInwardLoopback
32 dsx1FarEndPayloadLoopback
64 dsx1FarEndLineLoopback"
::= { dsx1ConfigEntry 18 }

dsxlDs1ChannelNumber OBJECT-TYPE
SYNTAX      INTEGER (0..28)
MAX-ACCESS  read-only
STATUS      current
DESCRIPTION  
"This variable represents the channel number of the DS1/E1 on its parent DS2/E2 or DS3/E3. A value of 0 indicates that this DS1/E1 does not have a parent DS3/E3."
::= { dsx1ConfigEntry 19 }

dsxlChannelization OBJECT-TYPE
SYNTAX      INTEGER {
            disabled(1),
            enabledDs0(2),
            disabledDs0(3),
            enabledDs1(4),
            disabledDs1(5),
            enabled(6),
            disabled(7),
            enabledDs2(8),

-- The DS1 Fractional Table

dsx1FracTable OBJECT-TYPE
SYNTAX SEQUENCE OF Dsx1FracEntry
MAX-ACCESS not-accessible
STATUS deprecated
DESCRIPTION
"This table is deprecated in favor of using ifStackTable.

The table was mandatory for systems dividing a DS1 into channels containing different data streams that are of local interest. Systems that are indifferent to data content, such as CSUs, need not implement it.

The DS1 Fractional table identifies which DS1 channels associated with a CSU are being used to support a logical interface, i.e., an entry in the interfaces table from the Internet-standard MIB.

For example, consider an application managing a North American ISDN Primary Rate link whose division is a 384-kbit/s H1 _B_ Channel for video,
a second H1 for data to a primary routing peer, and 12 64-kbit/s H0 B Channels. Consider that some subset of the H0 channels is used for voice and the remainder are available for dynamic data calls.

We count a total of 14 interfaces multiplexed onto the DS1 interface. Six DS1 channels (for the sake of the example, channels 1..6) are used for video, six more (7..11 and 13) are used for data, and the remaining 12 are in channels 12 and 14..24.

Let us further imagine that ifIndex 2 is of type DS1 and refers to the DS1 interface and that the interfaces layered onto it are numbered 3..16.

We might describe the allocation of channels, in the dsx1FracTable, as follows:

```
dsx1FracIfIndex.2. 1 = 3  dsx1FracIfIndex.2.13 = 4
dsx1FracIfIndex.2. 2 = 3  dsx1FracIfIndex.2.14 = 6
dsx1FracIfIndex.2. 3 = 3  dsx1FracIfIndex.2.15 = 7
dsx1FracIfIndex.2. 4 = 3  dsx1FracIfIndex.2.16 = 8
dsx1FracIfIndex.2. 5 = 3  dsx1FracIfIndex.2.17 = 9
dsx1FracIfIndex.2. 6 = 3  dsx1FracIfIndex.2.18 = 10
dsx1FracIfIndex.2. 7 = 4  dsx1FracIfIndex.2.19 = 11
dsx1FracIfIndex.2. 8 = 4  dsx1FracIfIndex.2.20 = 12
dsx1FracIfIndex.2. 9 = 4  dsx1FracIfIndex.2.21 = 13
dsx1FracIfIndex.2.10 = 4  dsx1FracIfIndex.2.22 = 14
dsx1FracIfIndex.2.11 = 4  dsx1FracIfIndex.2.23 = 15
dsx1FracIfIndex.2.12 = 5  dsx1FracIfIndex.2.24 = 16
```

For North American (DS1) interfaces, there are 24 legal channels, numbered 1 through 24.

For G.704 interfaces, there are 31 legal channels, numbered 1 through 31. The channels (1..31) correspond directly to the equivalently numbered time-slots.

5. Security Considerations

There are a number of management objects defined in this MIB module with a MAX-ACCESS clause of read-write. Such objects may be considered sensitive or vulnerable in some network environments. The support for SET operations in a non-secure environment without proper protection can have a negative effect on network operations. The specific objects and their sensitivities/vulnerabilities are as follows.

Setting the following objects to incorrect values may result in traffic interruptions:

- `dsx1LineType`
- `dsx1LineCoding`
- `dsx1SendCode`
- `dsx1LoopbackConfig`
- `dsx1SignalMode`
- `dsx1TransmitClockSource`
- `dsx1FdI`
- `dsx1LineLength`
- `dsx1Channelization`
- `dsx1LineMode`
- `dsx1LineBuildOut`
- `dsx1LineImpedance`

In the case of `dsx1LineType`, for example, both ends of a DS1/E1 must have the same value in order for traffic to flow. In the case of `dsx1SendCode` and `dsx1LoopbackConfig`, for another example, traffic may stop transmitting when particular loopbacks are applied.

Setting the following object to an incorrect value will not harm the traffic, but it may cause a circuit to be misidentified and thereby create difficulties for service personnel when attempting to troubleshoot a problem:

- `dsx1CircuitIdentifier`

Setting the following object can cause an increase in the number of traps received by the network management station:

- `dsx1LineStatusChangeTrapEnable`

The readable objects in this MIB module (i.e., the objects with a MAX-ACCESS other than not-accessible) may be considered sensitive in some environments since, collectively, they provide extensive information about the performance of interfaces in DS1/J1/E1/DS2/E2 equipment or networks and can reveal some aspects of their
configuration. In such environments, it is important to control even GET and NOTIFY access to these objects and possibly to encrypt the values of these objects when sending them over the network via SNMP.

SNMP versions prior to SNMPv3 did not include adequate security. Even if the network itself is secure (for example by using IPSec), even then, there is no control as to who on the secure network is allowed to access and GET/SET (read/change/create/delete) the objects in this MIB module.

It is RECOMMENDED that implementers consider the security features as provided by the SNMPv3 framework (see [RFC3410], section 8), including full support for the SNMPv3 cryptographic mechanisms (for authentication and privacy).

Further, deployment of SNMP versions prior to SNMPv3 is NOT RECOMMENDED. Instead, it is RECOMMENDED to deploy SNMPv3 and to enable cryptographic security. It is then a customer/operator responsibility to ensure that the SNMP entity giving access to an instance of this MIB module is properly configured to give access to the objects only to those principals (users) that have legitimate rights to indeed GET or SET (change/create/delete) them.

6. Acknowledgments

This document was produced by the AToM MIB Working Group.

Appendix A - Use of dsx1IfIndex and dsx1LineIndex

This appendix exists to document the previous use of dsx1IfIndex and dsx1LineIndex and to clarify the relationship of dsx1LineIndex as defined in RFC 1406 with the dsx1LineIndex as defined in this document.

The following shows the old and new definitions and the relationship:

[New Definition]: "This object should be made equal to ifIndex. The next paragraph describes its previous usage. Making the object equal to ifIndex allows proper use of ifStackTable and ds0/ds0bundle mibs.

[Old Definition]: "This object is the identifier of a DS1 Interface on a managed device. If there is an ifEntry that is directly associated with this and only this DS1 interface, it should have the same value as ifIndex. Otherwise, number the dsx1LineIndices with an unique identifier following the rules of choosing a number that is greater than ifNumber and numbering the inside interfaces (e.g., equipment side) with even numbers and outside interfaces (e.g., network side) with odd numbers."

When the "Old Definition" was created, it was described this way to allow a manager to treat the value as if it were an ifIndex; i.e., the value would be either: 1) an ifIndex value or 2) a value that was guaranteed to be different from all valid ifIndex values.

The new definition is a subset of that definition; i.e., the value is always an ifIndex value.

The following is Section 3.1 from RFC 1406:

Different physical configurations for the support of SNMP with DS1 equipment exist. To accommodate these scenarios, two different indices for DS1 interfaces are introduced in this MIB. These indices are dsx1IfIndex and dsx1LineIndex.

External interface scenario: the SNMP Agent represents all managed DS1 lines as external interfaces (for example, an Agent residing on the device supporting DS1 interfaces directly):

For this scenario, all interfaces are assigned an integer value equal to ifIndex, and the following applies:

ifIndex=dsx1IfIndex=dsx1LineIndex for all interfaces.
The dsx1IfIndex column of the DS1 Configuration table relates each DS1 interface to its corresponding interface (ifIndex) in the Internet-standard MIB (MIB-II STD 17, RFC 1213) [RFC1213].

External & Internal interface scenario: the SNMP Agents resides on a host external from the device supporting DS1 interfaces (e.g., a router). The Agent represents both the host and the DS1 device. The index dsx1LineIndex is used to not only represent the DS1 interfaces external from the host/DS1-device combination, but also the DS1 interfaces connecting the host and the DS1 device. The index dsx1IfIndex is always equal to ifIndex.

Example:

A shelf full of CSUs connected to a router. An SNMP Agent residing on the router proxies for itself and the CSU. The router has also an Ethernet interface:

```
+-----+               +---------------------+
|     |     |               |                     |
|     |     |  1.544 MBPS  |              Line#A |
|     |     |---------------+ - - - - -  - - -  - +---->
|     |     |               |                     |
|     |     |  1.544 MBPS  |              Line#B |
|     |     |---------------+ - - - - - - - - - - +---->
|     |     |               |  CSU Shelf          |
|     |     |  1.544 MBPS  |              Line#C |
|     |     |---------------+ - - - -- -- - - - - +---->
|     |     |               |                     |
|     |  E  |  1.544 MBPS  |              Line#D |
|     |     |---------------+ -  - - - -- - - - - +---->
|     |     |               |_____________________|
|-----|  R  |               |                   |
|     |     |
```

The assignment of the index values could for example be:

<table>
<thead>
<tr>
<th>ifIndex (= dsx1IfIndex)</th>
<th>dsx1LineIndex</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>NA</td>
</tr>
<tr>
<td>2</td>
<td>Line#A Router Side</td>
</tr>
<tr>
<td>3</td>
<td>Line#A Network Side</td>
</tr>
<tr>
<td>4</td>
<td>Line#B Router Side</td>
</tr>
<tr>
<td>5</td>
<td>Line#B Network Side</td>
</tr>
<tr>
<td>6</td>
<td>Line#C Router Side</td>
</tr>
<tr>
<td>7</td>
<td>Line#C Network Side</td>
</tr>
<tr>
<td>8</td>
<td>Line#D Router Side</td>
</tr>
<tr>
<td>9</td>
<td>Line#D Network Side</td>
</tr>
</tbody>
</table>

Nicklass, Ed.               Standards Track                    [Page 89]
For this example, ifNumber is equal to 5. Note the following description of dsxlLineIndex: the dsxlLineIndex identifies a DS1 Interface on a managed device. If there is an ifEntry that is directly associated with this and only this DS1 interface, it should have the same value as ifIndex. Otherwise, number the dsxlLineIndices with an unique identifier following the rules of choosing a number greater than ifNumber and numbering inside interfaces (e.g., equipment side) with even numbers and outside interfaces (e.g., network side) with odd numbers.

If the CSU shelf is managed by itself by a local SNMP Agent, the situation would be:

<table>
<thead>
<tr>
<th>ifIndex (= dsxlIfIndex)</th>
<th>dsxlLineIndex</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 Line#A Network Side</td>
<td>1</td>
</tr>
<tr>
<td>2 Line#A RouterSide</td>
<td>2</td>
</tr>
<tr>
<td>3 Line#B Network Side</td>
<td>3</td>
</tr>
<tr>
<td>4 Line#B RouterSide</td>
<td>4</td>
</tr>
<tr>
<td>5 Line#C Network Side</td>
<td>5</td>
</tr>
<tr>
<td>6 Line#C Router Side</td>
<td>6</td>
</tr>
<tr>
<td>7 Line#D Network Side</td>
<td>7</td>
</tr>
<tr>
<td>8 Line#D Router Side</td>
<td>8</td>
</tr>
</tbody>
</table>

Appendix B - The Delay Approach to Unavailable Seconds

This procedure is illustrated below for a DS1 ESF interface. Similar rules would apply for other DS1, DS2, and E1 interface variants. The procedure guarantees that the statistical counters are correctly updated at all times, although they lag real time by 10 seconds. At the end of each 15-minute interval, the current interval counts are transferred to the most recent interval entry and each interval is shifted up by one position, with the oldest being discarded if necessary in order to make room. The current interval counts then start over from zero. Note, however, that the signal state calculation does not start afresh at each interval boundary; rather, signal state information is retained across interval boundaries.
Note that if such a procedure is adopted, there is no current interval data for the first 10 seconds after a system comes up. noSuchInstance must be returned if a management station attempts to access the current interval counters during this time.

It is an implementation-specific matter whether an agent assumes that the initial state of the interface is available or unavailable.
Appendix C - Changes from Previous Versions

C.1. Changes from RFC 3895

The changes from RFC 3895 [RFC3895] are the following:

1. Values were added to dsx1LineType to support J1 types.
2. The object dsx1LineImpedance was added.
3. All DM-related objects were deprecated following their removal from ITU performance standards.
4. Relevant text and reference section were updated.
5. Changes in Compliance Statements to include new values.

C.2. Changes from RFC 2495

The changes from RFC 2495 [RFC2495] are the following:

1. The dsx1FracIfIndex SYNTAX matches the description range.
2. A value was added to dsx1TransmitClockSource.
3. Values were added to dsx1LineType.
4. Two objects were added, dsx1LineMode and dsx1LineBuildOut, to better express transceiver mode and LineBuildOut for T1.
5. Reference was added to Circuit Identifier object.
6. Align the DESCRIPTION clauses of few statistic objects with the near-end definition, with the far-end definition, and with [RFC3593].
7. Changes in Compliance Statements to include new objects.
8. A typographical error in dsx2E2 was fixed; new name is dsx1E2.

C.3. Changes from RFC 1406

The changes from RFC 1406 [RFC1406] are the following:

1. The Fractional table has been deprecated.
2. This document uses SMIv2.
3. Usage is given for ifTable and ifXTable.
4. Example usage of ifStackTable is included.
5. dsx1IfIndex has been deprecated.
6. Support for DS2 and E2 has been added.
7. Additional lineTypes for DS2, E2, and unframed E1 were added.
8. The definition of valid intervals has been clarified for the case where the agent proxied for other devices. In particular, the treatment of missing intervals has been clarified.
9. An inward loopback has been added.
10. Additional lineStatus bits have been added for Near End in Unavailable Signal State, Carrier Equipment Out of Service, DS2 Payload AIS, and DS2 Performance Threshold.
A read-write line Length object has been added.
Signal mode of other has been added.
Added a lineStatus last change, trap and enabler.
The e1(19) ifType has been obsoleted, so this MIB does not list it as a supported ifType.
Textual Conventions for statistics objects have been used.
A new object, dsxlLoopbackStatus, has been introduced to reflect the loopbacks established on a DS1 interface and the source to the requests. dsxlLoopbackConfig continues to be the desired loopback state while dsxlLoopbackStatus reflects the actual state.
A dual loopback has been added to allow the setting of an inward loopback and a line loopback at the same time.
An object indicating which channel to use within a parent object (i.e., DS3) has been added.
An object has been added to indicate whether or not this DS1/E1 is channelized.
Line coding type of B6ZS has been added for DS2.

C.4. Companion Documents

This document is a companion to the documents that define managed objects for the DS0 [RFC2494], DS3/E3 [RFC3896], and Synchronous Optical Network/Synchronous Digital Hierarchy (SONET/SDH) [RFC3592] Interface Types.
