Definitions of Managed Objects for IP Flow Information Export

Abstract

This document defines managed objects for IP Flow Information eXport (IPFIX). These objects provide information for monitoring IPFIX Exporters and IPFIX Collectors including the basic configuration information.

Status of This Memo

This is an Internet Standards Track document.

This document is a product of the Internet Engineering Task Force (IETF). It represents the consensus of the IETF community. It has received public review and has been approved for publication by the Internet Engineering Steering Group (IESG). Further information on Internet Standards is available in Section 2 of RFC 5741.

Information about the current status of this document, any errata, and how to provide feedback on it may be obtained at http://www.rfc-editor.org/info/rfc5815.

1. Introduction

This document defines two MIB modules for monitoring IP Flow Information eXport (IPFIX) Devices including Exporters and Collectors. Most of the objects defined by the IPFIX MIB module MUST be implemented. Some objects MAY be implemented corresponding to the functionality implemented in the equipment. Since the IPFIX architecture [RFC5470] foresees the possibility of using Filtering and/or Sampling functions to reduce the data volume, this document also provides the IPFIX SELECTOR MIB module, which contains the standardized selection methods and is controlled by IANA. The full configuration of the IPFIX Metering Process is out of the scope of these MIB modules.

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC 2119 [RFC2119].

2. IPFIX Documents Overview

The IPFIX protocol provides network administrators with access to IP Flow information. The architecture for the export of measured IP Flow information out of an IPFIX Exporting Process to a Collecting Process is defined in [RFC5470], per the requirements defined in [RFC3917]. The protocol document [RFC5101] specifies how IPFIX Data Records and Templates are carried via a congestion-aware transport protocol from IPFIX Exporting Processes to IPFIX Collecting Processes. IPFIX has a formal description of IPFIX Information Elements, their name, type and additional semantic information, as specified in [RFC5102]. Finally, [RFC5472] describes what type of applications can use the IPFIX protocol and how they can use the information provided. It furthermore shows how the IPFIX framework relates to other architectures and frameworks.

It is assumed that Flow metering, export, and collection is performed according to the IPFIX architecture defined in [RFC5470]. The monitored configuration parameters of the export and collection of Flow Templates and Data Records is modeled according to [RFC5101]. Packet selection methods that may be optionally used by the IPFIX Metering Process are not considered in this MIB module. They are defined in the Packet Sampling (PSAMP) framework [RFC5474] and Sampling techniques [RFC5475] documents. Nevertheless, the basis for defining Sampling and Filtering functions is given with the IPFIX SELECTOR MIB module. Since the PSAMP export protocol [RFC5476] is based on the IPFIX protocol, the Sampling and Filtering functions can be added to the IPFIX SELECTOR MIB module as needed.
3. The Internet-Standard Management Framework

For a detailed overview of the documents that describe the current Internet-Standard Management Framework, please refer to section 7 of RFC 3410 [RFC3410].

Managed objects are accessed via a virtual information store, termed the Management Information Base or MIB. MIB objects are generally accessed through the Simple Network Management Protocol (SNMP). Objects in the MIB are defined using the mechanisms defined in the Structure of Management Information (SMI). This memo specifies MIB modules that are compliant to the SMIv2, which is described in STD 58, RFC 2578 [RFC2578], STD 58, RFC 2579 [RFC2579] and STD 58, RFC 2580 [RFC2580].

4. Terminology

The definitions of the basic terms like IP Traffic Flow, Exporting Process, Collecting Process, Observation Points, etc. can be found in the IPFIX protocol document [RFC5101].

5. Structure of the IPFIX MIB

The IPFIX MIB module consists of seven main tables, the Transport Session table, the Template table and the corresponding Template Definition table, the Export table, the Metering Process table, the Observation Point table, and the Selection Process table. Since the IPFIX architecture [RFC5470] foresees the possibility of using Filtering and/or Sampling functions to reduce the data volume, the MIB module provides the basic objects for these functions with the Selection Process table. The IPFIX SELECTOR MIB module defined in the next section provides the standard Filtering and Sampling functions that can be referenced in the ipfixSelectionProcessTable.

All remaining objects contain statistical values for the different tables contained in the MIB module.

The following subsections describe all tables in the IPFIX MIB module.

5.1. The Transport Session Table

The Transport Session is the basis of the MIB module. The Transport Session table (ipfixTransportSessionTable) contains all Transport Sessions between Exporter and Collector. The table specifies the transport layer protocol of the Transport Session and, depending on that protocol, further parameters for the Transport Session. In the case of UDP and TCP, these are the source and destination address as
well as the source and destination port. For Stream Control
Transmission Protocol (SCTP), the table contains the SCTP Assoc Id,
which is the index for the SCTP association in the SCTP MIB module
[RFC3873]. The mode of operation of the device, i.e., if the
Transport Session is used for collecting or exporting is given in the
ipfixTransportSessionDeviceMode object. Further on, it contains the
configured refresh parameters for Templates and Options Templates
that are used across unreliable connections as UDP. Finally, the
IPFIX version that is exported or collected by this Transport Session
and a status of the Transport Session is given in the table.

To illustrate the use of the above tables, let us assume the
following scenario: we have an Exporter on IP address 192.0.2.22 and
a Collector on IP address 192.0.2.37. The Exporter uses TCP to
export Templates and Data Records. The same Exporter also exports,
with UDP, to a Collector with the IP address of 192.0.2.44. This
would lead to the following Transport Session table on the Exporter:
The values in brackets are the OID numbers. The Collectors would then have the same entry except that the index would most likely differ and the ipfixTransportSessionDeviceMode would be collecting(2).
5.2. The Template Table

The Template table lists all Templates (including Options Templates) that are sent (by an Exporter) or received (by a Collector). The (Options) Templates are unique per Transport Session, which also gives the device mode (Exporter or Collector) and Observation Domain; thus, the table is indexed by:

- the Transport Session Index (ipfixTransportSessionIndex)
- and the Observation Domain Id (ipfixTemplateObservationDomainId).

It contains the Set Id and an access time denoting the time when the (Options) Template was last sent or received.

To resume the above example, the Exporter may want to export a Template and an Options Template for each Transport Session defined above. This leads to the following Template table defining Template and Options Template:
We assume that the Transport Session that is stored with index 5 in the Transport Session table of the Exporter is stored with index 17 in the Transport Session table of the (corresponding) Collector. Then, the Template table would look as follows:

```
ipfixTemplateTable (3)
ipfixTemplateEntry (1)
  index (5) (ipfixTransportSessionIndex)
    index (3) (ipfixTemplateObservationDomainId)
      index (257) (ipfixTemplateId)
        ipfixTemplateObservationDomainId (1) = 3
        ipfixTemplateId (2) = 257
        ipfixTemplateSetId (3) = 2
        ipfixTemplateAccessTime (4)
          = 2008-7-1,12:49:11.2,+2:0
      index (264) (ipfixTemplateId)
        ipfixTemplateObservationDomainId (1) = 3
        ipfixTemplateId (2) = 264
        ipfixTemplateSetId (3) = 3
        ipfixTemplateAccessTime (4)
          = 2008-7-1,12:47:04.8,+2:0
    index (11) (ipfixTransportSessionIndex)
      index (3) (ipfixTemplateObservationDomainId)
        index (273) (ipfixTemplateId)
          ipfixTemplateObservationDomainId (1) = 3
          ipfixTemplateId (2) = 273
          ipfixTemplateSetId (3) = 2
          ipfixTemplateAccessTime (4)
            = 2008-7-1,12:49:11.2,+2:0
        index (289) (ipfixTemplateId)
          ipfixTemplateObservationDomainId (1) = 3
          ipfixTemplateId (2) = 289
          ipfixTemplateSetId (3) = 3
          ipfixTemplateAccessTime (4)
            = 2008-7-1,12:47:04.8,+2:0
```
The table on the second Collector would be analogous to the one shown above.

5.3. The Template Definition Table

To resume the above example again, the Exporter is configured to export the octets received and dropped at the Observation Point since the last export of these values. In addition, it exports the start and end time of the Flow relative to the timestamp contained in the IPFIX header. This leads to the following Template Definition table on the Exporter:
The corresponding table entry on the Collector is the same except that it would have another ipfixTransportSessionIndex, e.g., 17 as in the previous example.
5.4. The Export Table

On Exporters, the Export table (ipfixExportTable) can be used to support features like failover, load-balancing, duplicate export to several Collectors, etc. The table has three indexes that link an entry with:

- the Metering Process table (ipfixMeteringProcessCacheId, see below)
- and the Transport Session table (ipfixTransportSessionIndex).

Those entries with the same ipfixExportIndex and the same ipfixMeteringProcessCacheId define a Transport Session group. The member type for each group member describes its functionality. All Transport Sessions referenced in this table MUST have the ipfixTransportSessionDeviceMode exporting(1).

If the Exporter does not use Transport Session grouping, then each ipfixExportIndex contains a single ipfixMeteringProcessCacheId, and thus a single Transport Session (ipfixTransportSessionIndex) and this session MUST have the member type primary(1).

For failover, a Transport Session group can contain one Transport Session with member type "primary" and several Transport Sessions with type secondary(2). Entries with other member types are not allowed for that type of group. For load-balancing or parallel export, all Transport Sessions in the group MUST have the same member type, either loadBalancing(4) or parallel(3).

The algorithms used for failover or load-balancing are out of the scope of this document.

To continue the example, we assume that the Exporter uses the two connections shown in the examples above as one primary Transport Session protected by a secondary Transport Session. The Exporter then has the following entries in the ipfixExportTable:
The example shows that the Exporter uses the Metering Process Cache 9, explained below, to export IPFIX Data Records for the Transport Sessions 5 and 11. The Templates 257 and 264 defined above are exported within Transport Session 5, and the Templates 273 and 289 are exported within Transport Session 11. If we assume that Templates 257 and 264 are identical, then the Collector that receives Transport Session 11 is a backup for the Collector of Transport Session 5.

5.5. The Metering Process Table

The Metering Process, as defined in [RFC5101], consists of a set of functions. Maintaining the Flow Records is one of them. This function is responsible for passing the Flow Records to the Exporting Process and also for detecting Flow expiration. The Flow Records that are maintained by the Metering Process can be grouped by the Observation Points at which they are observed. The instance that maintains such a group of Flow Records is a kind of cache. For this reason, the Metering Process table (ipfixMeteringProcessTable) is indexed by cache Ids (ipfixMeteringProcessCacheId). Each cache can be maintained by a separate instance of the Metering Process. To specify the Observation Point(s) where the Flow Records are gathered, the ipfixMeteringProcessObservationPointGroupRef may contain an ipfixObservationPointGroupId from the Observation Point table (ipfixObservationPointTable) described in the next section. If an
Observation Point is not specified for the Flow Records, the `ipfixMeteringProcessObservationPointGroupRef` MUST be zero(0). The timeouts (`ipfixMeteringProcessCacheActiveTimeout` and `ipfixMeteringProcessCacheInactiveTimeout`) specify when Flows are expired.

```
ipfixMeteringProcessTable (6)
  |
  +- ipfixMeteringProcessEntry (1)
    |         |         |         |
    +- index (9) (ipfixMeteringProcessCacheId)
      +- ipfixMeteringProcessCacheId (1) = 9
      +- ipfixMeteringProcessObservationPointGroupRef (2) = 17
      +- ipfixMeteringProcessCacheActiveTimeout (3) = 100
      +- ipfixMeteringProcessCacheInactiveTimeout (4) = 100
```

5.6. The Observation Point Table

The Observation Point table (ipfixObservationPointTable) groups Observation Points with the `ipfixObservationPointGroupId`. Each entry contains the Observation Domain Id in which the Observation Point is located and a reference to the ENTITY MIB module [RFC4133] or the IF MIB module [RFC2863]. The objects in the ENTITY MIB module referenced by `ipfixObservationPointPhysicalEntity` or IF MIB module referenced by `ipfixObservationPointPhysicalInterface` denote the Observation Point. If no such index can be given in those modules, the references MUST be 0. If a reference is given in both object `ipfixObservationPointPhysicalEntity` and `ipfixObservationPointPhysicalInterface`, then both MUST point to the same physical interface. In addition, a direction can be given to render more specifically which Flow to monitor.
5.7. The Selection Process Table

This table supports the usage of Filtering and Sampling functions, as described in [RFC5470]. It contains lists of functions per Metering Process cache (ipfixMeteringProcessCacheId). The selection process index ipfixSelectionProcessIndex forms groups of selection methods that are applied to an observed packet stream. The selection process selector index (ipfixSelectionProcessSelectorIndex) indicates the order in which the functions are applied to the packets observed at the Observation Points associated with the Metering Process cache. The selection methods are applied in increasing order, i.e., selection methods with a lower ipfixSelectionProcessSelectorIndex are applied first. The functions are referred by object identifiers pointing to the function with its parameters. If the selection method does not use parameters, then it MUST point to the root of the function subtree (see also Section 6). If the function uses parameters, then it MUST point to an entry in the parameter table of the selection method. If no Filtering or Sampling function is used for a Metering Process, then an entry for the Metering Process SHOULD be created pointing to the Select All function (ipfixFuncSelectAll).
5.8. The Statistical Tables

For the ipfixTransportSessionTable, the ipfixTemplateTable, the ipfixMeteringProcessTable, and the ipfixSelectionProcessTable statistical tables are defined that augment those tables. All the statistical tables contain a discontinuity object that holds a timestamp that denotes the time when a discontinuity event occurred to notify the management system that the counters contained in those tables might not be continuous anymore.

5.8.1. The Transport Session Statistical Table

The Transport Session Statistical table (ipfixTransportSessionStatsTable) augments the ipfixTransportSessionTable with statistical values. It contains the rate (in bytes per second) with which it receives or sends out IPFIX Messages, the number of bytes, packets, messages, Records, Templates and Options Templates received or sent and the number of messages that were discarded.

5.8.2. The Template Statistical Table

This table contains a statistical value for each Template. It augments the Template table (ipfixTemplateTable) and specifies the number of Data Records exported or collected for the Template.

5.8.3. The Metering Process Statistical Table

This table augments the Metering Process table (ipfixMeteringProcessTable). It contains the statistical values for the exported Data Records and the number of unused cache entries.

5.8.4. The Selection Process Statistical Table

This table augments the Selection Process table (ipfixSelectionProcessTable) and introduces two generic statistical values, the number of packets observed and the number of packets dropped by the selection method.

6. Structure of the IPFIX SELECTOR MIB

The IPFIX SELECTOR MIB module defined in this section provides the standard Filtering and Sampling functions that can be referenced in the ipfixSelectionProcessTable. The subtree ipfixSelectorFunctions is a placeholder where all standard Filtering and Sampling functions should be located. It currently contains the Select All function (ipfixFuncSelectAll). The IPFIX SELECTOR MIB module is maintained by IANA and can be extended through Expert Review [RFC5226], i.e.,
review by one of a group of experts designated by an IETF Area Director. The group of experts MUST check the requested MIB objects for completeness and accuracy of the description. Requests for MIB objects that duplicate the functionality of existing objects SHOULD be declined. The smallest available OID SHOULD be assigned to a new MIB objects. The specification of new MIB objects SHOULD follow the structure specified in the next Section and MUST be published using a well-established and persistent publication medium. The experts will initially be drawn from the Working Group Chairs and document editors of the IPFIX and PSAMP Working Groups.

6.1. The Selector Functions

The following figure shows what the MIB tree usually should look like. It already contains the ipfixFuncSelectAll. The subtree in ipfixFuncF2 gives the basic structure that all selection methods SHOULD follow.

```
ipfixSelectorFunctions
  |  
  +- ipfixFuncSelectAll
  |  
  |  +- ipfixFuncSelectAllAvail (is the function available?)
  `
  +- ipfixFuncF2
  |  
  |  +- ipfixFuncF2Avail (is the function F2 available?)
  |  
  |  +- ipfixFuncF2Parameters (a table with parameters)
  ...
  `-- ipfixFunFn...
```

The selection method SHOULD be designed as a MIB subtree introduced by an object with the name ipfixFunc appended by a function name. The objects in this subtree SHOULD be prefixed by this name. If the function is named Fx, then we would start a subtree with an OID named ipfixFuncFx. This subtree should contain an object ipfixFuncFxAvail that has the type TruthValue. If a selection method takes parameters, the MIB should contain a table named ipfixFuncFxParameters, which should contain all the parameters that the selection method specifies. An entry in this table will be referenced by the IPFIX MIB module if the selection method with the parameters is used.
To illustrate the structure defined above, the following contains an example of a function MyFunc that holds three integer parameters Param1, Param2, and Param3. In the example, there are currently two instances of the parameters set defined with indexes 1 and 4.

```
ipfixSelectorFunctions (1)
| +-- ipfixFuncMyFunc (?)
  | | +-- ipfixFuncMyFuncAvail (1) = true
  | | +-- ipfixFuncMyFuncParameters (2)
  |     | +-- ipfixFuncMyFuncParametersEntry (1)
  |     |     | +-- index (1) (ipfixFuncMyFuncParametersIndex)
  |     |     |     | +-- ipfixFuncMyFuncParam1 (1) = 47
  |     |     |     | +-- ipfixFuncMyFuncParam2 (2) = -128
  |     |     |     | +-- ipfixFuncMyFuncParam3 (3) = 19
  |     | +-- index(4) (ipfixFuncMyFuncParametersIndex)
  |     | +-- ipfixFuncMyFuncParam1 (1) = 19
  |     | +-- ipfixFuncMyFuncParam2 (2) = -1
  |     | +-- ipfixFuncMyFuncParam3 (3) = 728
```

If the function defined above is referenced in the IPFIX MIB module, the ipfixSelectionProcessTable would look as follows:

```
ipfixSelectionProcessTable (8)
| +-- ipfixSelectionProcessEntry (1)
  | | +-- index (9) (ipfixMeteringProcessCacheId)
  |     | +-- index (1) (ipfixSelectionProcessIndex)
  |     |     | +-- index (1) (ipfixSelectionProcessSelectorIndex)
  |     |     |     | +-- ipfixSelectionProcessSelectorFunction (3)
  |     |     |     |     | = ipfixSelectorFunctions.?.2.1.4
  |     |     | +-- index (2) (ipfixSelectionProcessSelectorIndex)
  |     |     |     | +-- ipfixSelectionProcessSelectorFunction (3)
  |     |     |     |     | = ipfixSelectorFunctions.?.2.1.1
```

This means that for the ipfixMeteringProcessCacheId(9), a Selection Process with index 1 is created that applies two times the same function but with different parameter sets. First, the function MyFunc is applied with the parameters of the set with index 4 and the with the parameters of the set with index 1.
7. Relationship to Other MIB Modules

Besides the usual imports from the SNMP Standards [RFC2578], [RFC2579], and [RFC2580], the IPFIX MIB module references the ENTITY MIB module [RFC4133] and the IF MIB module [RFC2863].

7.1. Relationship to the ENTITY MIB and IF MIB

The Observation Point table (ipfixObservationPointTable) contains a reference to the ENTITY MIB module [RFC4133] (ipfixObservationPointPhysicalEntity) or the IF MIB module [RFC2863] (ipfixObservationPointPhysicalInterface). If the implementors of the IPFIX MIB module want to specify the physical entity where Flows are observed, then they SHOULD also implement the ENTITY MIB and/or the IF MIB module. The implementation of the ENTITY MIB and/or IF MIB module is OPTIONAL. If one of them is not implemented, then all values of the respective column ipfixObservationPointPhysicalEntity or ipfixObservationPointPhysicalInterface in the Observation Point table are zero and the values of the ipfixObservationPointPhysicalEntityDirection columns are unknown(0), if none of them are defined.

7.2. MIB Modules Required for IMPORTS

The IPFIX MIB module requires the modules SNMPv2-SMI [RFC2578], SNMPv2-TC [RFC2579], and SNMPv2-CONF [RFC2580]. Further on, it imports the textual conventions InetAddressType and InetAddress from the INET ADDRESS MIB module [RFC4001].

The IPFIX SELECTOR MIB module also requires the modules SNMPv2-SMI [RFC2578], SNMPv2-TC [RFC2579], and SNMPv2-CONF [RFC2580].

8. MIB Definitions

This section contains the definitions of the IPFIX-MIB module and the IPFIX-SELECTOR-MIB module. There are different mandatory groups defined for Collector and Exporter implementations. The statistical objects are made OPTIONAL.
8.1.  IPFIX MIB Definition

-- 1.1.4: Export Table

ipfixExportTable  OBJECT-TYPE
   SYNTAX      SEQUENCE OF IpfixExportEntry
   MAX-ACCESS  not-accessible
   STATUS      current
   DESCRIPTION
   "This table lists all exports of an IPFIX device."
On Exporters, this table contains all exports grouped by Transport Session, Observation Domain Id, Template Id, and Metering Process represented by the ipfixMeteringProcessCacheId. Thanks to the ipfixExportIndex, the exports can group one or more Transport Sessions to achieve a special functionality like failover management, load-balancing, etc. The entries with the same ipfixExportIndex, ipfixObservationDomainId, and ipfixMeteringProcessCacheId define a Transport Session group. If the Exporter does not use Transport Session grouping, then each ipfixExportIndex contains a single ipfixMeteringProcessCacheId and thus a single Transport Session, and this session MUST have the member type primary(1). Transport Sessions referenced in this table MUST have the ipfixTransportSessionDeviceMode exporting(1).

On Collectors, this table is not needed.

::= { ipfixMainObjects 4 }

    ipfixExportMemberType     INTEGER
}

ipfixExportIndex OBJECT-TYPE
SYNTAX Unsigned32 (1..4294967295)
MAX-ACCESS not-accessible
STATUS current
DESCRIPTION
"Locally arbitrary, but unique identifier of an entry in the ipfixExportTable. The value is expected to remain constant from a re-initialization of the entity’s network management agent to the next re-initialization.
A common ipfixExportIndex between two entries from this table expresses that there is a relationship between the Transport Sessions in ipfixTransportSessionIndex. The type of relationship is expressed by the value of ipfixExportMemberType.

::= { ipfixExportEntry 1 }

ipfixExportMemberType OBJECT-TYPE
SYNTAX INTEGER {
    unknown(0),
    primary(1),
    secondary(2),
    parallel(3),
    loadBalancing(4)
}

MAX-ACCESS read-only
STATUS current
DESCRIPTION
"The type of a member Transport Session in a Transport Session group (identified by the value of ipfixExportIndex, ipfixObservationDomainId, and ipfixMeteringProcessCacheId). The following values are valid:

unknown(0)
    This value MUST be used if the status of the group membership cannot be detected by the equipment. This value should be avoided as far as possible.

primary(1)
    This value is used for a group member that is used as the primary target of an Exporter. Other group members (with the same ipfixExportIndex and ipfixMeteringProcessCacheId) MUST NOT have the value primary(1) but MUST have the value secondary(2). This value MUST also be specified if the Exporter does not support Transport Session grouping. In this case, the group contains only one Transport Session.

secondary(2)
    This value is used for a group member that is used as a secondary target of an Exporter. The Exporter will use one of the targets specified as secondary(2) within the same Transport Session group when the primary target is not reachable."
parallel(3)
This value is used for a group member that is used for
duplicate exporting, i.e., all group members identified
by the ipfixExportIndex are exporting the same Records
in parallel. This implies that all group members MUST
have the same membertype parallel(3).

loadBalancing(4)
This value is used for a group member that is used
as one target for load-balancing. This means that a
Record is sent to one of the group members in this
group identified by ipfixExportIndex.
This implies that all group members MUST have the same
membertype loadBalancing(4)."

STATUS      current
DESCRIPTION
"Locally arbitrary, but unique identifier of an entry in the
ipfixObservationPointTable. The value is expected to remain
constant from a re-initialization of the entity’s network
management agent to the next re-initialization.

This index represents a group of Observation Points.

The special value of 0 MUST NOT be used within this table
but is reserved for the usage in the
ipfixMeteringProcessTable. An index of 0 for the
ipfixObservationPointGroupReference index in that table
indicates that an Observation Point is unknown or
unspecified for a Metering Process cache."
::= { ipfixObservationPointEntry 1 }

ipfixObservationPointIndex OBJECT-TYPE
SYNTAX      Unsigned32 (1..4294967295)
MAX-ACCESS  not-accessible
STATUS      current
DESCRIPTION
"Locally arbitrary, but unique identifier of an entry in the
ipfixObservationPointTable. The value is expected to remain
constant from a re-initialization of the entity’s network
management agent to the next re-initialization.

This index represents a single Observation Point in an
Observation Point group."
::= { ipfixObservationPointEntry 2 }

ipfixObservationPointObservationDomainId OBJECT-TYPE
SYNTAX      Unsigned32
MAX-ACCESS  read-only
STATUS      current

Dietz, et al.                Standards Track                   [Page 40]
DESCRIPTION

"The Id of the Observation Domain in which this Observation Point is included.

The special value of 0 indicates that the Observation Points within this group cannot be applied to a single Observation Domain."

REFERENCE

 ::= { ipfixObservationPointEntry 3 }

ipfixObservationPointPhysicalEntity OBJECT-TYPE
SYNTAX      PhysicalIndexOrZero
MAX-ACCESS  read-only
STATUS      current
DESCRIPTION

"This object contains the index of a physical entity in the ENTITY MIB. This physical entity is the given Observation Point. If such a physical entity cannot be specified or is not known, then the object is zero."

 ::= { ipfixObservationPointEntry 4 }

ipfixObservationPointPhysicalInterface OBJECT-TYPE
SYNTAX      InterfaceIndexOrZero
MAX-ACCESS  read-only
STATUS      current
DESCRIPTION

"This object contains the index of a physical interface in the IF MIB. This physical interface is the given Observation Point. If such a physical interface cannot be specified or is not known, then the object is zero.

This object MAY be used stand alone or in addition to ipfixObservationPointPhysicalEntity. If ipfixObservationPointPhysicalEntity is not zero, this object MUST point to the same physical interface that is referenced in ipfixObservationPointPhysicalEntity. Otherwise, it may reference any interface in the IF MIB."

 ::= { ipfixObservationPointEntry 5 }
ipfixObservationPointPhysicalEntityDirection OBJECT-TYPE
SYNTAX      INTEGER {
    unknown(0),
    ingress(1),
    egress(2),
    both(3)
}
MAX-ACCESS  read-only
STATUS      current
DESCRIPTION
"The direction of the Flow that is monitored on the given physical entity. The following values are valid:

unknown(0)
This value MUST be used if a direction is not known for the given physical entity.

ingress(1)
This value is used for monitoring incoming Flows on the given physical entity.

egress(2)
This value is used for monitoring outgoing Flows on the given physical entity.

both(3)
This value is used for monitoring incoming and outgoing Flows on the given physical entity."
::= { ipfixObservationPointEntry 6 }

-- 1.1.7: Selection Process Table

ipfixSelectionProcessTable OBJECT-TYPE
SYNTAX      SEQUENCE OF IpfixSelectionProcessEntry
MAX-ACCESS  not-accessible
STATUS      current
DESCRIPTION
"This table contains Selector Functions connected to a Metering Process by the index ipfixMeteringProcessCacheId. The Selector Functions are grouped into Selection Processes by the ipfixSelectionProcessIndex. The Selector Functions are applied within the Selection Process to the packets observed for the given Metering Process cache in increasing order implied by the ipfixSelectionProcessSelectorIndex. This means Selector Functions with lower ipfixSelectionProcessSelectorIndex are applied first. The remaining packets are accounted for in Flow Records."
Since IPFIX does not define any Selector Function (except selecting every packet), this is a placeholder for future use and a guideline for implementing enterprise-specific Selector Function objects.

The following object tree should visualize how the Selector Function objects should be implemented:

```
ipfixSelectorFunctions
  | +-- ipfixFuncSelectAll
  |     | +-- ipfixFuncSelectAllAvail (is the function available?)
  | +-- ipfixFuncF2
  |     | +-- ipfixFuncF2Avail (is the function F2 available?)
  |     |     | +-- ipfixFuncF2Parameters (a table with parameters)
  |     |     ...'
  | +-- ipfixFunFn...
```

If a Selector Function takes parameters, the MIB should contain a table with an entry for each set of parameters used at the Exporter.

```

ipfixSelectionProcessSelectorIndex OBJECT-TYPE
SYNTAX    Unsigned32 (1..4294967295)
MAX-ACCESS not-accessible
STATUS     current
DESCRIPTION
"Index specifying the order in which the referenced
ipfixSelectionProcessSelectorFunctions are applied to the
observed packet stream within the given Selection Process
(identified by the ipfixSelectionProcessIndex). The
Selector Functions are applied in increasing order, i.e.,
Selector Functions with lower index are applied first."
::= { ipfixSelectionProcessEntry 2 }

ipfixSelectionProcessSelectorFunction OBJECT-TYPE
SYNTAX    OBJECT IDENTIFIER
MAX-ACCESS read-only
STATUS     current
DESCRIPTION
"The pointer to the Selector Function used at position
ipfixSelectionProcessSelectorIndex in the list of Selector
Functions for the Metering Process cache specified by the
index ipfixMeteringProcessCacheId and for the given
Selection Process (identified by the
ipfixSelectionProcessIndex).

This usually points to an object in the IPFIX SELECTOR MIB.
If the Selector Function does not take parameters, then it
MUST point to the root of the function subtree. If the
function takes parameters, then it MUST point to an entry
in the parameter table of the Selector Function."

DESCRIPTION

"The IPFIX SELECTOR MIB module defines the standard filtering and sampling functions that can be referenced in the ipfixSelectorTable of the IPFIX MIB. The subtree ipfixSelectorFunctions is a placeholder where all standard filtering and sampling functions should be located.

The IPFIX SELECTOR MIB module is maintained by IANA and can be extended through Expert Review [RFC5226], i.e., review by one of a group of experts designated by an IETF Area

Director. The group of experts MUST check the requested MIB objects for completeness and accuracy of the description. Requests for MIB objects that duplicate the functionality of existing objects SHOULD be declined. The smallest available OID SHOULD be assigned to a new MIB objects. The specification of new MIB objects SHOULD follow the structure specified in RFC 5815 and MUST be published using a well-established and persistent publication medium. The experts will initially be drawn from the Working Group Chairs and document editors of the IPFIX and PSAMP Working Groups.

9. Security Considerations

There are no management objects defined in this MIB module that have a MAX-ACCESS clause of read-write and/or read-create. So, if these MIB modules are implemented correctly, then there is no risk that an intruder can alter or create any management objects of these MIB modules via direct SNMP SET operations.

Some of the readable objects in these MIB modules (i.e., objects with a MAX-ACCESS other than not-accessible) may be considered sensitive or vulnerable in some network environments. It is thus important to control even GET and/or NOTIFY access to these objects and possibly to even encrypt the values of these objects when sending them over the network via SNMP. These are the tables and objects and their sensitivity/vulnerability:

- ipfixTransportSessionTable - contains configuration data that might be sensitive because objects in this table may reveal information about the network infrastructure
- ipfixExportTable - contains configuration data that might be sensitive because objects in this table may reveal information about the network infrastructure as well
- ipfixMeteringProcessTable - contains configuration data that might be sensitive because objects in this table may reveal information about the IPFIX Device itself
- ipfixObservationPointTable - contains configuration data that might be sensitive because objects in this table may reveal information about the IPFIX Device itself and the network infrastructure
- ipfixSelectorFunctions - currently contains no sensitive data but might want to be secured anyway since it may contain sensitive data in a future version

All other objects and tables contain no data that is considered sensitive.
SNMP versions prior to SNMPv3 did not include adequate security. Even if the network itself is secure (for example by using IPsec), even then, there is no control as to who on the secure network is allowed to access and GET/SET (read/change/create/delete) the objects in these MIB modules.

It is RECOMMENDED that implementers consider the security features as provided by the SNMPv3 framework (see [RFC3410] Section 8), including full support for the SNMPv3 cryptographic mechanisms (for authentication and privacy).

Further, deployment of SNMP versions prior to SNMPv3 is NOT RECOMMENDED. Instead, it is RECOMMENDED to deploy SNMPv3 and to enable cryptographic security. It is then a customer/operator responsibility to ensure that the SNMP entity giving access to an instance of these MIB modules is properly configured to give access to the objects only to those principals (users) that have legitimate rights to indeed GET or SET (change/create/delete) them.

10. IANA Considerations

The MIB module in this document uses the following IANA-assigned OBJECT IDENTIFIER values recorded in the SMI Numbers registry:

<table>
<thead>
<tr>
<th>Descriptor</th>
<th>OBJECT IDENTIFIER value</th>
</tr>
</thead>
<tbody>
<tr>
<td>ipfixMIB</td>
<td>{ mib-2 193 }</td>
</tr>
<tr>
<td>ipfixSelectorMIB</td>
<td>{ mib-2 194 }</td>
</tr>
</tbody>
</table>

Further on, the whole IPFIX SELECTOR MIB module is maintained by IANA. Additions to this MIB module are subject to Expert Review [RFC5226], i.e., review by one of a group of experts designated by an IETF Area Director. The group of experts MUST check the requested MIB objects for completeness and accuracy of the description. Requests for MIB objects that duplicate the functionality of existing objects SHOULD be declined. The smallest available OID SHOULD be assigned to new MIB objects. The specification of new MIB objects SHOULD follow the structure specified in Section 6 and MUST be published using a well-established and persistent publication medium. The experts will initially be drawn from the Working Group Chairs and document editors of the IPFIX and PSAMP Working Groups.

11. Acknowledgments

This document is a product of the IPFIX Working Group. The authors would like to thank the following persons: Paul Aitken for his detailed review, Dan Romascanu and the MIB doctors, and many more, for the technical reviews and feedback.
