YANG Module for NETCONF Monitoring

Abstract

This document defines a Network Configuration Protocol (NETCONF) data model to be used to monitor the NETCONF protocol. The monitoring data model includes information about NETCONF datastores, sessions, locks, and statistics. This data facilitates the management of a NETCONF server. This document also defines methods for NETCONF clients to discover data models supported by a NETCONF server and defines a new NETCONF <get-schema> operation to retrieve them.

Status of This Memo

This is an Internet Standards Track document.

This document is a product of the Internet Engineering Task Force (IETF). It represents the consensus of the IETF community. It has received public review and has been approved for publication by the Internet Engineering Steering Group (IESG). Further information on Internet Standards is available in Section 2 of RFC 5741.

Information about the current status of this document, any errata, and how to provide feedback on it may be obtained at http://www.rfc-editor.org/info/rfc6022.

1. Introduction

This document defines a YANG [RFC6020] model to be used to monitor the NETCONF protocol. It provides information about NETCONF sessions and supported schema as defined in [RFC4741].

Considerations such as different schema formats, feature optionality, and access controls can all impact the applicability and level of detail the NETCONF server sends to a client during session setup. The methods defined in this document address the need for further means to query and retrieve schema and NETCONF state information from a NETCONF server. These are provided to complement existing base NETCONF capabilities and operations and in no way affect existing behaviour.

A new <get-schema> operation is also defined to support explicit schema retrieval via NETCONF.

1.1. Definition of Terms

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [RFC2119].

2. Data Model to Monitor NETCONF

The NETCONF monitoring data model defined in this document provides operational information on the NETCONF server. This includes details specific to the NETCONF protocol (e.g., protocol-specific counters such as 'in-sessions') as well as data related to schema retrieval (e.g., schema list).

A server that implements the data model defined in this document ("urn:ietf:params:xml:ns:yang:ietf-netconf-monitoring") MUST advertise the capability URI as described in [RFC6020].

This section presents an overview of the monitoring data model. For detailed descriptions, refer to the normative YANG module provided in this document (see Section 5).

2.1. The /netconf-state Subtree

The netconf-state container is the root of the monitoring data model.
netconf-state
   /capabilities
   /datastores
   /schemas
   /sessions
   /statistics

capabilities
   List of NETCONF capabilities supported by the server.

datastores
   List of NETCONF configuration datastores (e.g., running, startup, candidate) supported on this device and related information.

schemas
   List of schemas supported on the server. Includes all the information required to identify the schemas and to support their retrieval.

sessions
   List of all active NETCONF sessions on the device. Includes per-session counters for all NETCONF sessions.

statistics
   Includes global counters for the NETCONF server.

2.1.1. The /netconf-state/capabilities Subtree

The /netconf-state/capabilities subtree contains the capabilities supported by the NETCONF server. The list MUST include all capabilities exchanged during session setup still applicable at the time of the request.

2.1.2. The /netconf-state/datastores Subtree

The /netconf-state/datastores subtree contains the list of available datastores for the NETCONF server and includes information on their lock state.

datastore
   /name
   /locks

name (leaf, netconf-datastore-type)
   Enumeration of supported datastores; candidate, running, startup.
locks (grouping, lock-info)
List of locks for the datastore. Information is provided for both
global and partial locks [RFC5717]. For partial locks, the list
of locked nodes and the select expressions originally used to
request the lock are returned.

2.1.3. The /netconf-state/schemas Subtree

The list of supported schema for the NETCONF server.

    schema
       /identifier   (key)
       /version      (key)
       /format       (key)
       /namespace
       /location

The elements identifier, version, and format are used as a key in the
schema list. These are used in the <get-schema> operation.

identifier (string)
Identifier for the schema list entry. The identifier is used in
the <get-schema> operation and may be used for other means such as
file retrieval.

version (string)
Version of the schema supported. Multiple versions MAY be
supported simultaneously by a NETCONF server. Each version MUST
be reported individually in the schema list, i.e., with same
identifier, possibly different location, but different version.

For YANG data models, version is the value of the most recent YANG
‘revision’ statement in the module or submodule, or the empty
string if no ‘revision’ statement is present.

format (identifyref, schema-format)
The data modeling language the schema is written in. The data
modeling language is represented as a YANG identity. This
document defines the identities "xsd", "yang", "yin", "rng", and
"rnc" (see Section 5).

namespace (inet:uri)
The Extensible Markup Language (XML) namespace [XML-NAMES] defined
by the schema.
location (union: enum, inet:uri)
    One or more locations from which this specific schema can be retrieved. The list SHOULD contain at least one entry per schema.

2.1.4. The /netconf-state/sessions Subtree

Includes session-specific data for NETCONF management sessions. The session list MUST include all currently active NETCONF sessions.

session
    /session-id (key)
    /transport
    /username
    /source-host
    /login-time
    /in-rpcs
    /in-bad-rpcs
    /out-rpc-errors
    /out-notifications

session-id (uint32, 1..max)
    Unique identifier for the session. This value is the NETCONF session identifier, as defined in [RFC4741].

transport (identityref, transport)
    Identifies the transport for each session. The transport is represented as a YANG identity. This document defines the identities "netconf-ssh", "netconf-soap-over-beep", "netconf-soap-over-https", "netconf-beep", and "netconf-tls" (see Section 5).

username (string)
    The username is the client identity that was authenticated by the NETCONF transport protocol. The algorithm used to derive the username is NETCONF transport protocol specific and in addition specific to the authentication mechanism used by the NETCONF transport protocol.

source-host (inet:host)
    Host identifier (IP address or name) of the NETCONF client.

login-time (yang:date-and-time)
    Time at the server at which the session was established.

in-rpcs (yang:zero-based-counter32)
    Number of correct <rpc> messages received.
in-bad-rpcs (yang:zero-based-counter32)
   Number of messages received when an <rpc> message was expected,
   that were not correct <rpc> messages. This includes XML parse
erserrs and errors on the rpc layer.

out-rpc-errors (yang:zero-based-counter32)
   Number of <rpc-reply> messages sent that contained an <rpc-error>
   element.

out-notifications (yang:zero-based-counter32)
   Number of <notification> messages sent.

2.1.5. The /netconf-state/statistics Subtree

Statistical data pertaining to the NETCONF server.

statistics
   /netconf-start-time
   /in-bad-hellos
   /in-sessions
   /dropped-sessions
   /in-rpcs
   /in-bad-rpcs
   /out-rpc-errors
   /out-notifications

statistics:
   Contains management-session-related performance data for the
   NETCONF server.

netconf-start-time (yang:date-and-time)
   Date and time at which the management subsystem was started.

in-bad-hellos (yang:zero-based-counter32)
   Number of sessions silently dropped because an invalid <hello>
   message was received.

in-sessions (yang:zero-based-counter32)
   Number of sessions started.

dropped-sessions (yang:zero-based-counter32)
   Number of sessions that were abnormally terminated, e.g., due to
   idle timeout or transport close.

in-rpcs (yang:zero-based-counter32)
   Number of correct <rpc> messages received.
in-bad-rpcs (yang:zero-based-counter32)
   Number of messages received when an <rpc> message was expected,
   which were not correct <rpc> messages.

out-rpc-errors (yang:zero-based-counter32)
   Number of <rpc-reply> messages sent that contained an <rpc-error>
   element.

out-notifications (yang:zero-based-counter32)
   Number of <notification> messages sent.

3. Schema Specific Operations

3.1. The <get-schema> Operation

Description:

   This operation is used to retrieve a schema from the NETCONF
   server.

Parameters:

   identifier (string):
      Identifier for the schema list entry.
      Mandatory parameter.

   version (string):
      Version of the schema requested.
      Optional parameter.

   format (identityref, schema-format):
      The data modeling language of the schema.
      Default value is ‘yang’ when not specified.
      Optional parameter.

Positive Response:

   The NETCONF server returns the requested schema.

Negative Response:

   If the requested schema does not exist, the <error-tag> is
   ’invalid-value’.

   If more than one schema matches the requested parameters, the
   <error-tag> is ’operation-failed’, and <error-app-tag> is
   ’data-not-unique’.
4. Examples

4.1. Retrieving Schema List via <get> Operation

A NETCONF client retrieves the list of supported schema from a NETCONF server by retrieving the /netconf-state/schemas subtree via a <get> operation.

Available schema for the requesting session are returned in the reply containing the <identifier>, <version>, <format>, and <location> elements.

The response data can be used to determine the available schema and their versions. The schema itself (i.e., schema content) is not returned in the response. The optional <location> element contains a URI, which can be used to retrieve the schema by another protocol such as ftp [RFC0959] or http(s) [RFC2616] [RFC2818], or the special value ‘NETCONF’, which means that the schema can be retrieved from the device via the <get-schema> operation.

Example:

```
<rpc message-id="101"
     xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get>
    <filter type="subtree">
        <schemas/>
      </netconf-state>
    </filter>
  </get>
</rpc>
```

The NETCONF server returns a list of schema available for retrieval.
<rpc-reply message-id="101"
    xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
    <data>
        <netconf-state
            xmlns="urn:ietf:params:xml:ns:yang:ietf-netconf-monitoring">
            <schemas>
                <schema>
                    <identifier>foo</identifier>
                    <version>1.0</version>
                    <format>xsd</format>
                    <namespace>http://example.com/foo</namespace>
                    <location>ftp://ftp.example.com/schemas/foo_1.0.xsd</location>
                    <location>http://www.example.com/schema/foo_1.0.xsd</location>
                    <location>NETCONF</location>
                </schema>
                <schema>
                    <identifier>foo</identifier>
                    <version>1.1</version>
                    <format>xsd</format>
                    <namespace>http://example.com/foo</namespace>
                    <location>ftp://ftp.example.com/schemas/foo_1.1.xsd</location>
                    <location>http://www.example.com/schema/foo_1.1.xsd</location>
                    <location>NETCONF</location>
                </schema>
                <schema>
                    <identifier>bar</identifier>
                    <version>2008-06-01</version>
                    <format>yang</format>
                    <namespace>http://example.com/bar</namespace>
                    <location>
                        http://example.com/schema/bar@2008-06-01.yang
                    </location>
                    <location>NETCONF</location>
                </schema>
                <schema>
                    <identifier>bar-types</identifier>
                    <version>2008-06-01</version>
                    <format>yang</format>
                    <namespace>http://example.com/bar</namespace>
                    <location>
                        http://example.com/schema/bar-types@2008-06-01.yang
                    </location>
                    <location>NETCONF</location>
                </schema>
            </schemas>
        </netconf-state>
    </data>
</rpc-reply>
4.2. Retrieving Schema Instances

Given the reply in the previous section, the following examples illustrate the retrieval of ‘foo’, ‘bar’, and ‘bar-types’ schema at multiple locations, with multiple formats, and in multiple locations.

1. foo, version 1.0 in xsd format:
   a. Via FTP using location
      ftp://ftp.example.com/schemas/foo_1.0.xsd
   b. Via HTTP using location
      http://www.example.com/schema/foo_1.0.xsd
   c. Via <get-schema> using identifier, version, and format parameters.

      <rpc message-id="101"
        xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
        <get-schema
          xmlns="urn:ietf:params:xml:ns:yang:ietf-netconf-monitoring">
          <identifier>foo</identifier>
          <version>1.0</version>
          <format>xsd</format>
        </get-schema>
      </rpc>

      <rpc-reply message-id="101"
        xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
        <data
          xmlns="urn:ietf:params:xml:ns:yang:ietf-netconf-monitoring">
          <xs:schema xmlns:xs="http://www.w3.org/2001/XMLSchema">
            <!-- foo 1.0 xsd schema contents here -->
          </xs:schema>
        </data>
      </rpc-reply>

2. bar, version 2008-06-01 in YANG format:
   a. Via HTTP using location
      http://example.com/schema/bar@2008-06-01.yang
   b. Via <get-schema> using identifier and version parameters:
3. bar-types, version 2008-06-01 in default YANG format:

a. Via <get-schema> using identifier parameter:

```xml
<rpc message-id="103"
    xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-schema
    xmlns="urn:ietf:params:xml:ns:yang:ietf-netconf-monitoring">
    <identifier>bar-types</identifier>
  </get-schema>
</rpc>

<rpc-reply message-id="103"
    xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data
    xmlns="urn:ietf:params:xml:ns:yang:ietf-netconf-monitoring">
    module bar-types {
      //default format (yang) returned
      //latest revision returned
      //is version 2008-06-01 yang module
      //contents here ...
    }
  </data>
</rpc-reply>
```
5. NETCONF Monitoring Data Model

The data model described in this memo is defined in the following YANG module.

This YANG module imports typedefs from [RFC6021] and references [RFC4741], [RFC4742], [RFC4743], [RFC4744], [RFC5539], [xmlschema-1], [RFC6020], [ISO/IEC19757-2:2008], and [RFC5717].

    described above.";
  }
}
6. Security Considerations

The YANG module defined in this memo is designed to be accessed via the NETCONF protocol [RFC4741]. The lowest NETCONF layer is the secure transport layer and the mandatory to implement secure transport is SSH [RFC4742].

Some of the readable data nodes in this YANG module may be considered sensitive or vulnerable in some network environments. It is thus important to control read access (e.g., via get, get-config, or notification) to these data nodes.

These are the containers, list nodes, and data nodes with their specific sensitivity/vulnerability:

/netconf-state/sessions/session/username: Contains identity information that could be used in an attempt to authenticate with the server.

This username is only meant for monitoring, and SHOULD NOT be used for other purposes, such as access control, without a detailed discussion of the limitations of this reported username. For example, it is possible that server A and server B might report the same username, but these might be for different persons.
7. Acknowledgements

The authors would like to thank Andy Bierman, Mehmet Ersue, Washam Fan, David Harrington, Balazs Lengyel, Hideki Okita, Juergen Schoenwaelder, Bert Wijnen, and many other members of the NETCONF WG for providing important input to this document. The authors would also like to specifically acknowledge Sharon Chisholm’s work on "NETCONF Monitoring Schema" [NETCONF] and contribution to this document.

8. IANA Considerations

This document registers one URI in "The IETF XML Registry". Following the format in [RFC3688], the following has been registered.

Registrant Contact: The IESG.
XML: N/A, the requested URI is an XML namespace.

This document registers one module in the "YANG Module Names" registry. Following the format in [RFC6020], the following has been registered.

name: ietf-netconf-monitoring
prefix: ncm
reference: RFC 6022
