Elliptic Curves for Security

Abstract

This memo specifies two elliptic curves over prime fields that offer a high level of practical security in cryptographic applications, including Transport Layer Security (TLS). These curves are intended to operate at the ~128-bit and ~224-bit security level, respectively, and are generated deterministically based on a list of required properties.

Status of This Memo

This document is not an Internet Standards Track specification; it is published for informational purposes.

This document is a product of the Internet Research Task Force (IRTF). The IRTF publishes the results of Internet-related research and development activities. These results might not be suitable for deployment. This RFC represents the consensus of the Crypto Forum Research Group of the Internet Research Task Force (IRTF). Documents approved for publication by the IRSG are not a candidate for any level of Internet Standard; see Section 2 of RFC 5741.

Information about the current status of this document, any errata, and how to provide feedback on it may be obtained at http://www.rfc-editor.org/info/rfc7748.

Since the initial standardization of Elliptic Curve Cryptography (ECC \[\text{RFC6090}\]) in \[\text{SEC1}\], there has been significant progress related to both efficiency and security of curves and implementations. Notable examples are algorithms protected against certain side-channel attacks, various "special" prime shapes that allow faster modular arithmetic, and a larger set of curve models from which to choose. There is also concern in the community regarding the generation and potential weaknesses of the curves defined by NIST \[\text{NIST}\].

This memo specifies two elliptic curves ("curve25519" and "curve448") that lend themselves to constant-time implementation and an exception-free scalar multiplication that is resistant to a wide range of side-channel attacks, including timing and cache attacks. They are Montgomery curves (where $v^2 = u^3 + A*u^2 + u$) and thus have birationally equivalent Edwards versions. Edwards curves support the fastest (currently known) complete formulas for the elliptic-curve group operations, specifically the Edwards curve $x^2 + y^2 = 1 + d*x^2*y^2$ for primes $p$ when $p = 3 \text{ mod } 4$, and the twisted Edwards curve $-x^2 + y^2 = 1 + d*x^2*y^2$ when $p = 1 \text{ mod } 4$. The maps to/from the Montgomery curves to their (twisted) Edwards equivalents are also given.
This memo also specifies how these curves can be used with the Diffie-Hellman protocol for key agreement.

2. Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC 2119 [RFC2119].

3. Notation

Throughout this document, the following notation is used:

- **p**: Denotes the prime number defining the underlying field.
- **GF(p)**: The finite field with p elements.
- **A**: An element in the finite field GF(p), not equal to -2 or 2.
- **d**: A non-zero element in the finite field GF(p), not equal to 1, in the case of an Edwards curve, or not equal to -1, in the case of a twisted Edwards curve.
- **order**: The order of the prime-order subgroup.
- **P**: A generator point defined over GF(p) of prime order.
- **U(P)**: The u-coordinate of the elliptic curve point P on a Montgomery curve.
- **V(P)**: The v-coordinate of the elliptic curve point P on a Montgomery curve.
- **X(P)**: The x-coordinate of the elliptic curve point P on a (twisted) Edwards curve.
- **Y(P)**: The y-coordinate of the elliptic curve point P on a (twisted) Edwards curve.
- **u, v**: Coordinates on a Montgomery curve.
- **x, y**: Coordinates on a (twisted) Edwards curve.
4.  Recommended Curves

4.1.  Curve25519

For the ~128-bit security level, the prime $2^{255} - 19$ is recommended for performance on a wide range of architectures. Few primes of the form $2^c - s$ with $s$ small exist between $2^{250}$ and $2^{521}$, and other choices of coefficient are not as competitive in performance. This prime is congruent to 1 mod 4, and the derivation procedure in Appendix A results in the following Montgomery curve $v^2 = u^3 + A*u^2 + u$, called "curve25519":

\[
p = 2^{255} - 19
\]
\[
A = 486662
\]
\[
\text{order} = 2^{252} + \text{0x1}4\text{def}9\text{dea}2\text{f}79\text{cd}65\text{81}2\text{6}31\text{a}5\text{cf}5\text{d}3\text{ed}
\]
\[
\text{cofactor} = 8
\]
\[
\text{U}(P) = 9
\]
\[
\text{V}(P) = 3775586237401
\]

The base point is $u = 9$, $v = 147816194475895447910205935684099868872646061346164752889648818$
\[
3775586237401
\]

This curve is birationally equivalent to a twisted Edwards curve $-x^2 + y^2 = 1 + d*x^2*y^2$, called "edwards25519", where:

\[
p = 2^{255} - 19
\]
\[
d = 370957059346694393431380835087545651895421138798432190163887855330$
\[
85940283555
\]
\[
\text{order} = 2^{252} + \text{0x1}4\text{def}9\text{dea}2\text{f}79\text{cd}65\text{81}2\text{6}31\text{a}5\text{cf}5\text{d}3\text{ed}
\]
\[
\text{cofactor} = 8
\]
\[
\text{X}(P) = 151122213495354007725011514095885315114540126930418572060461132$
\[
83949847762202
\]
\[
\text{Y}(P) = 463168356949264781694283940034751631413079938662562256157830336$
\[
03165251855960
\]
The birational maps are:

\[(u, v) = ((1+y)/(1-y), \sqrt{-486664} \cdot u/x)\]
\[(x, y) = (\sqrt{-486664} \cdot u/v, (u-1)/(u+1))\]

The Montgomery curve defined here is equal to the one defined in [curve25519], and the equivalent twisted Edwards curve is equal to the one defined in [ed25519].

4.2. Curve448

For the ~224-bit security level, the prime \(2^{448} - 2^{224} - 1\) is recommended for performance on a wide range of architectures. This prime is congruent to 3 mod 4, and the derivation procedure in Appendix A results in the following Montgomery curve, called "curve448":

\[
p = 2^{448} - 2^{224} - 1
\]
\[
A = 156326
\]
\[
\text{order} = 2^{446} - 0x8335dc163bb124b65129c96fde933d8d723a70aad873d6d54a7bb0d
\]
\[
\text{cofactor} = 4
\]
\[
U(P) = 5
\]
\[
V(P) = 355293926785568175264127502063783334808976399387714271831880898435169088786967410002932673765864550910142774147268105838985595290606362
\]

This curve is birationally equivalent to the Edwards curve \(x^2 + y^2 = 1 + d \cdot x^2 \cdot y^2\) where:

\[
p = 2^{448} - 2^{224} - 1
\]
\[
d = 61197585074452917616042322096555317543219696871016626328968936415087860042636474891785599283666020414768678979989378147065462815545017
\]
\[
\text{order} = 2^{446} - 0x8335dc163bb124b65129c96fde933d8d723a70aad873d6d54a7bb0d
\]
\[
\text{cofactor} = 4
\]
The birational maps are:

\[(u, v) = ((y-1)/(y+1), \sqrt{156324}\cdot u/x)\]
\[(x, y) = (\sqrt{156324}\cdot u/v, (1+u)/(1-u))\]

Both of those curves are also 4-isogenous to the following Edwards curve \(x^2 + y^2 = 1 + d\cdot x^2\cdot y^2\), called "edwards448", where:

\[p = 2^{448} - 2^{224} - 1\]
\[d = -39081\]
\[order = 2^{446} - 0x8335dc163bb124b65129c96fde933d8d723a70aad873d6d54a7bb0d\]
\[cofactor = 4\]

The 4-isogeny maps between the Montgomery curve and this Edwards curve are:

\[(u, v) = (y^2/x^2, (2 - x^2 - y^2)\cdot y/x^3)\]
\[(x, y) = (4\cdot v\cdot (u^2 - 1)/(u^4 - 2\cdot u^2 + 4\cdot v^2 + 1),\]
\[-(u^5 - 2\cdot u^3 - 4\cdot u\cdot v^2 + u)/\]
\[(u^5 - 2\cdot u^2\cdot v^2 - 2\cdot u^3 - 2\cdot v^2 + u))\]

The curve edwards448 defined here is also called "Goldilocks" and is equal to the one defined in [goldilocks].
5. The X25519 and X448 Functions

The "X25519" and "X448" functions perform scalar multiplication on the Montgomery form of the above curves. (This is used when implementing Diffie-Hellman.) The functions take a scalar and a u-coordinate as inputs and produce a u-coordinate as output. Although the functions work internally with integers, the inputs and outputs are 32-byte strings (for X25519) or 56-byte strings (for X448) and this specification defines their encoding.

The u-coordinates are elements of the underlying field GF(2^255 - 19) or GF(2^448 - 2^224 - 1) and are encoded as an array of bytes, u, in little-endian order such that u[0] + 256*u[1] + 256^2*u[2] + ... + 256^(n-1)*u[n-1] is congruent to the value modulo p and u[n-1] is minimal. When receiving such an array, implementations of X25519 (but not X448) MUST mask the most significant bit in the final byte. This is done to preserve compatibility with point formats that reserve the sign bit for use in other protocols and to increase resistance to implementation fingerprinting.

Implementations MUST accept non-canonical values and process them as if they had been reduced modulo the field prime. The non-canonical values are 2^255 - 19 through 2^255 - 1 for X25519 and 2^448 - 2^224 - 1 through 2^448 - 1 for X448.

The following functions implement this in Python, although the Python code is not intended to be performant nor side-channel free. Here, the "bits" parameter should be set to 255 for X25519 and 448 for X448:

```python
<CODE BEGINS>
def decodeLittleEndian(b, bits):
    return sum([b[i] << 8*i for i in range((bits+7)/8)])

def decodeUCoordinate(u, bits):
    u_list = [ord(b) for b in u]
    # Ignore any unused bits.
    if bits % 8:
        u_list[-1] &= (1<<(bits%8))-1
    return decodeLittleEndian(u_list, bits)

def encodeUCoordinate(u, bits):
    u = u % p
    return ''.join([chr((u >> 8*i) & 0xff)
                   for i in range((bits+7)/8)])
<CODE ENDS>
```
Scalars are assumed to be randomly generated bytes. For X25519, in order to decode 32 random bytes as an integer scalar, set the three least significant bits of the first byte and the most significant bit of the last to zero, set the second most significant bit of the last byte to 1 and, finally, decode as little-endian. This means that the resulting integer is of the form $2^{254} + 8$ times a value between 0 and $2^{251} - 1$ (inclusive). Likewise, for X448, set the two least significant bits of the first byte to 0, and the most significant bit of the last byte to 1. This means that the resulting integer is of the form $2^{447} + 4$ times a value between 0 and $2^{445} - 1$ (inclusive).

```python
def decodeScalar25519(k):
    k_list = [ord(b) for b in k]
    k_list[0] &= 248
    k_list[31] &= 127
    k_list[31] |= 64
    return decodeLittleEndian(k_list, 255)

def decodeScalar448(k):
    k_list = [ord(b) for b in k]
    k_list[0] &= 252
    k_list[55] |= 128
    return decodeLittleEndian(k_list, 448)
<CODE ENDS>

To implement the X25519(k, u) and X448(k, u) functions (where k is the scalar and u is the u-coordinate), first decode k and u and then perform the following procedure, which is taken from [curve25519] and based on formulas from [montgomery]. All calculations are performed in GF(p), i.e., they are performed modulo p. The constant a24 is $(486662 - 2) / 4 = 121665$ for curve25519/X25519 and $(156326 - 2) / 4 = 39081$ for curve448/X448.
\[ x_1 = u \]
\[ x_2 = 1 \]
\[ z_2 = 0 \]
\[ x_3 = u \]
\[ z_3 = 1 \]
\[ \text{swap} = 0 \]

For \( t = \text{bits}-1 \) down to 0:

\[ k_t = (k >> t) & 1 \]
\[ \text{swap} ^= k_t \]

// Conditional swap; see text below.

\[ (x_2, x_3) = \text{cswap}(\text{swap}, x_2, x_3) \]
\[ (z_2, z_3) = \text{cswap}(\text{swap}, z_2, z_3) \]
\[ \text{swap} = k_t \]

\[ A = x_2 + z_2 \]
\[ AA = A^2 \]
\[ B = x_2 - z_2 \]
\[ BB = B^2 \]
\[ E = AA - BB \]
\[ C = x_3 + z_3 \]
\[ D = x_3 - z_3 \]
\[ DA = D * A \]
\[ CB = C * B \]
\[ x_3 = (DA + CB)^2 \]
\[ z_3 = x_1 * (DA - CB)^2 \]
\[ x_2 = AA * BB \]
\[ z_2 = E * (AA + a24 * E) \]

// Conditional swap; see text below.

\[ (x_2, x_3) = \text{cswap}(\text{swap}, x_2, x_3) \]
\[ (z_2, z_3) = \text{cswap}(\text{swap}, z_2, z_3) \]

Return \( x_2 \cdot (z_2^{(p - 2)}) \)

(Note that these formulas are slightly different from Montgomery’s original paper. Implementations are free to use any correct formulas.)

Finally, encode the resulting value as 32 or 56 bytes in little-endian order. For X25519, the unused, most significant bit MUST be zero.)
The cswap function SHOULD be implemented in constant time (i.e.,
independent of the swap argument). For example, this can be done as
follows:

cswap(swap, x_2, x_3):
    dummy = mask(swap) AND (x_2 XOR x_3)
    x_2 = x_2 XOR dummy
    x_3 = x_3 XOR dummy
    Return (x_2, x_3)

Where mask(swap) is the all-1 or all-0 word of the same length as x_2
and x_3, computed, e.g., as mask(swap) = 0 - swap.

5.1.  Side-Channel Considerations

X25519 and X448 are designed so that fast, constant-time
implementations are easier to produce. The procedure above ensures
that the same sequence of field operations is performed for all
values of the secret key, thus eliminating a common source of side-
channel leakage. However, this alone does not prevent all side-
channels by itself. It is important that the pattern of memory
accesses and jumps not depend on the values of any of the bits of k.
It is also important that the arithmetic used not leak information
about the integers modulo p, for example by having b*c be
distinguishable from c*c. On some architectures, even primitive
machine instructions, such as single-word division, can have variable
timing based on their inputs.

Side-channel attacks are an active research area that still sees
significant, new results. Implementors are advised to follow this
research closely.
5.2. Test Vectors

Two types of tests are provided. The first is a pair of test vectors for each function that consist of expected outputs for the given inputs. The inputs are generally given as 64 or 112 hexadecimal digits that need to be decoded as 32 or 56 binary bytes before processing.

X25519:

Input scalar:

The second type of test vector consists of the result of calling the function in question a specified number of times. Initially, set $k$ and $u$ to be the following values:

For X25519:

0900000000000000000000000000000000000000000000000000000000000000

For X448:

05000000000000000000000000000000000000000000000000000000
00000000000000000000000000000000000000000000000000000000

For each iteration, set $k$ to be the result of calling the function and $u$ to be the old value of $k$. The final result is the value left in $k$.

X25519:

After one iteration:

422c8e7a6227d7bca1350b3e2bb7279f7897b87bb6854b783c60e80311ae3079

After 1,000 iterations:

6. Diffie-Hellman

6.1. Curve25519

The X25519 function can be used in an Elliptic Curve Diffie-Hellman (ECDH) protocol as follows:

Alice generates 32 random bytes in a[0] to a[31] and transmits \( K_A = X25519(a, 9) \) to Bob, where 9 is the u-coordinate of the base point and is encoded as a byte with value 9, followed by 31 zero bytes.

Bob similarly generates 32 random bytes in b[0] to b[31], computes \( K_B = X25519(b, 9) \), and transmits it to Alice.

Using their generated values and the received input, Alice computes \( X25519(a, K_B) \) and Bob computes \( X25519(b, K_A) \).

Both now share \( K = X25519(a, X25519(b, 9)) = X25519(b, X25519(a, 9)) \) as a shared secret. Both MAY check, without leaking extra information about the value of K, whether K is the all-zero value and abort if so (see below). Alice and Bob can then use a key-derivation function that includes K, K_A, and K_B to derive a symmetric key.

The check for the all-zero value results from the fact that the X25519 function produces that value if it operates on an input corresponding to a point with small order, where the order divides the cofactor of the curve (see Section 7). The check may be performed by ORing all the bytes together and checking whether the result is zero, as this eliminates standard side-channels in software implementations.

Test vector:

Alice’s private key, a:

77076d0a7318a57d3c16c17251b26645df4c2f87ebc0992ab177fba51db92c2a

Alice’s public key, X25519(a, 9):

6.2. Curve448

The X448 function can be used in an ECDH protocol very much like the X25519 function.

If X448 is to be used, the only differences are that Alice and Bob generate 56 random bytes (not 32) and calculate $K_A = \text{X448}(a, 5)$ or $K_B = \text{X448}(b, 5)$, where $5$ is the u-coordinate of the base point and is encoded as a byte with value $5$, followed by $55$ zero bytes.

As with X25519, both sides MAY check, without leaking extra information about the value of $K$, whether the resulting shared $K$ is the all-zero value and abort if so.

Test vector:

Alice’s private key, $a$:
9a8f4925d1519f5775cf46b04b5800d4ee9ee8bae8bc5565d498c28d

7. Security Considerations

The security level (i.e., the number of "operations" needed for a brute-force attack on a primitive) of curve25519 is slightly under the standard 128-bit level. This is acceptable because the standard security levels are primarily driven by much simpler, symmetric primitives where the security level naturally falls on a power of two. For asymmetric primitives, rigidly adhering to a power-of-two security level would require compromises in other parts of the design, which we reject. Additionally, comparing security levels between types of primitives can be misleading under common threat models where multiple targets can be attacked concurrently [bruteforce].
The ~224-bit security level of curve448 is a trade-off between performance and paranoia. Large quantum computers, if ever created, will break both curve25519 and curve448, and reasonable projections of the abilities of classical computers conclude that curve25519 is perfectly safe. However, some designs have relaxed performance requirements and wish to hedge against some amount of analytical advance against elliptic curves and thus curve448 is also provided.

Protocol designers using Diffie-Hellman over the curves defined in this document must not assume "contributory behaviour". Specially, contributory behaviour means that both parties' private keys contribute to the resulting shared key. Since curve25519 and curve448 have cofactors of 8 and 4 (respectively), an input point of small order will eliminate any contribution from the other party's private key. This situation can be detected by checking for the all-zero output, which implementations MAY do, as specified in Section 6. However, a large number of existing implementations do not do this.

Designers using these curves should be aware that for each public key, there are several publicly computable public keys that are equivalent to it, i.e., they produce the same shared secrets. Thus using a public key as an identifier and knowledge of a shared secret as proof of ownership (without including the public keys in the key derivation) might lead to subtle vulnerabilities.

Designers should also be aware that implementations of these curves might not use the Montgomery ladder as specified in this document, but could use generic, elliptic-curve libraries instead. These implementations could reject points on the twist and could reject non-minimal field elements. While not recommended, such implementations will interoperate with the Montgomery ladder specified here but may be trivially distinguishable from it. For example, sending a non-canonical value or a point on the twist may cause such implementations to produce an observable error while an implementation that follows the design in this text would successfully produce a shared key.

Appendix A. Deterministic Generation

This section specifies the procedure that was used to generate the above curves; specifically, it defines how to generate the parameter A of the Montgomery curve \( y^2 = x^3 + A x^2 + x \). This procedure is intended to be as objective as can reasonably be achieved so that it’s clear that no untoward considerations influenced the choice of curve. The input to this process is \( p \), the prime that defines the underlying field. The size of \( p \) determines the amount of work needed to compute a discrete logarithm in the elliptic curve group, and choosing a precise \( p \) depends on many implementation concerns. The performance of the curve will be dominated by operations in \( \text{GF}(p) \), so carefully choosing a value that allows for easy reductions on the intended architecture is critical. This document does not attempt to articulate all these considerations.

The value \( (A-2)/4 \) is used in several of the elliptic curve point arithmetic formulas. For simplicity and performance reasons, it is beneficial to make this constant small, i.e., to choose \( A \) so that \( (A-2) \) is a small integer that is divisible by four.

For each curve at a specific security level:

1. The trace of Frobenius MUST NOT be in \{0, 1\} in order to rule out the attacks described in [smart], [satoh], and [semaev], as in [brainpool] and [safecurves].

2. MOV Degree [reducing]: the embedding degree MUST be greater than \((\text{order} - 1) / 100\), as in [brainpool] and [safecurves].

3. CM Discriminant: discriminant \( D \) MUST be greater than \( 2^{100} \), as in [safecurves].
A.1.  \( p = 1 \mod 4 \)

For primes congruent to 1 mod 4, the minimal cofactors of the curve and its twist are either \( \{4, 8\} \) or \( \{8, 4\} \). We choose a curve with the latter cofactors so that any algorithms that take the cofactor into account don’t have to worry about checking for points on the twist, because the twist cofactor will be the smaller of the two.

To generate the Montgomery curve, we find the minimal, positive \( A \) value such that \( A > 2 \) and \( (A-2) \) is divisible by four and where the cofactors are as desired. The `find1Mod4` function in the following Sage script returns this value given \( p \):

```python
<CODE BEGINS>
def findCurve(prime, curveCofactor, twistCofactor):
    F = GF(prime)
    for A in xrange(3, int(1e9)):
        if (A-2) % 4 != 0:
            continue
        try:
            E = EllipticCurve(F, [0, A, 0, 1, 0])
        except:
            continue
        groupOrder = E.order()
        twistOrder = 2*(prime+1) - groupOrder
        if (groupOrder % curveCofactor == 0 and
            is_prime(groupOrder // curveCofactor) and
            twistOrder % twistCofactor == 0 and
            is_prime(twistOrder // twistCofactor)):
            return A

def find1Mod4(prime):
    assert((prime % 4) == 1)
    return findCurve(prime, 8, 4)
<CODE ENDS>
```

Generating a curve where \( p = 1 \mod 4 \)
A.2.  p = 3 mod 4

For a prime congruent to 3 mod 4, both the curve and twist cofactors can be 4, and this is minimal. Thus, we choose the curve with these cofactors and minimal, positive A such that A > 2 and (A-2) is divisible by four. The find3Mod4 function in the following Sage script returns this value given p:

<CODE BEGINS>
def find3Mod4(prime):
    assert((prime % 4) == 3)
    return findCurve(prime, 4, 4)
<CODE ENDS>

Generating a curve where p = 3 mod 4

A.3.  Base Points

The base point for a curve is the point with minimal, positive u value that is in the correct subgroup. The findBasepoint function in the following Sage script returns this value given p and A:

<CODE BEGINS>
def findBasepoint(prime, A):
    F = GF(prime)
    E = EllipticCurve(F, [0, A, 0, 1, 0])
    
    for uInt in range(1, 1e3):
        u = F(uInt)
        v2 = u^3 + A*u^2 + u
        if not v2.is_square():
            continue
        v = v2.sqrt()
        point = E(u, v)
        pointOrder = point.order()
        if pointOrder > 8 and pointOrder.is_prime():
            return point
<CODE ENDS>

Generating the base point
Acknowledgements

This document is the result of a combination of draft-black-rpgecc-01 and draft-turner-thecurve25519function-01. The following authors of those documents wrote much of the text and figures but are not listed as authors on this document: Benjamin Black, Joppe W. Bos, Craig Costello, Patrick Longa, Michael Naehrig, Watson Ladd, and Rich Salz.

The authors would also like to thank Tanja Lange, Rene Struik, Rich Salz, Ilari Liusvaara, Deirdre Connolly, Simon Josefsson, Stephen Farrell, Georg Nestmann, Trevor Perrin, and John Mattsson for their reviews and contributions.

The X25519 function was developed by Daniel J. Bernstein in [curve25519].
