Well-Known Uniform Resource Identifiers (URIs)

Abstract

This memo defines a path prefix for "well-known locations", "/.well-known/", in selected Uniform Resource Identifier (URI) schemes.

In doing so, it obsoletes RFC 5785 and updates the URI schemes defined in RFC 7230 to reserve that space. It also updates RFC 7595 to track URI schemes that support well-known URIs in their registry.

Status of This Memo

This is an Internet Standards Track document.

This document is a product of the Internet Engineering Task Force (IETF). It represents the consensus of the IETF community. It has received public review and has been approved for publication by the Internet Engineering Steering Group (IESG). Further information on Internet Standards is available in Section 2 of RFC 7841.

Information about the current status of this document, any errata, and how to provide feedback on it may be obtained at https://www.rfc-editor.org/info/rfc8615.

1. Introduction

Some applications on the Web require the discovery of information about an origin [RFC6454] (sometimes called "site-wide metadata") before making a request. For example, the Robots Exclusion Protocol (http://www.robotstxt.org) specifies a way for automated processes to obtain permission to access resources; likewise, the Platform for Privacy Preferences [P3P] tells user agents how to discover privacy policy before interacting with an origin server.

While there are several ways to access per-resource metadata (e.g., HTTP header fields, PROPFIND in Web Distributed Authoring and Versioning (WebDAV) [RFC4918]), the perceived overhead (either in terms of client-perceived latency and/or deployment difficulties) associated with them often precludes their use in these scenarios.

At the same time, it has become more popular to use HTTP as a substrate for non-Web protocols. Sometimes, such protocols need a way to locate one or more resources on a given host.

When this happens, one solution is to designate a "well-known location" for data or services related to the origin overall, so that it can be easily located. However, this approach has the drawback of risking collisions, both with other such designated "well-known locations" and with resources that the origin has created (or wishes to create). Furthermore, defining well-known locations usurps the origin’s control over its own URI space [RFC7320].
To address these uses, this memo reserves a path prefix in HTTP, HTTPS, WebSocket (WS), and Secure WebSocket (WSS) URIs for these "well-known locations", "/.well-known/". Future specifications that need to define a resource for such metadata can register their use to avoid collisions and minimise impingement upon origins’ URI space.

Well-known URIs can also be used with other URI schemes, but only when those schemes’ definitions explicitly allow it.

2. Notational Conventions

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [RFC2119] [RFC8174] when, and only when, they appear in all capitals, as shown here.

3. Well-Known URIs

A well-known URI is a URI [RFC3986] whose path component begins with the characters "/.well-known/", provided that the scheme is explicitly defined to support well-known URIs.

For example, if an application registers the name ‘example’, the corresponding well-known URI on ‘http://www.example.com/’ would be ‘http://www.example.com/.well-known/example’.

This specification updates the "http" [RFC7230] and "https" [RFC7230] schemes to support well-known URIs. Other existing schemes can use the appropriate process for updating their definitions; for example, [RFC8307] does so for the "ws" and "wss" schemes. The "Uniform Resource Identifier (URI) Schemes" registry tracks which schemes support well-known URIs; see Section 5.2.

Applications that wish to mint new well-known URIs MUST register them, following the procedures in Section 5.1, subject to the following requirements.

Registered names MUST conform to the "segment-nz" production in [RFC3986]. This means they cannot contain the "/" character.

Registered names for a specific application SHOULD be correspondingly precise; "squatting" on generic terms is not encouraged. For example, if the Example application wants a well-known location for metadata, an appropriate registered name might be "example-metadata" or even "example.com-metadata", not "metadata".
At a minimum, a registration will reference a specification that defines the format and associated media type(s) to be obtained by dereferencing the well-known URI, along with the URI scheme(s) that the well-known URI can be used with. If no URI schemes are explicitly specified, "http" and "https" are assumed.

Typically, applications will use the default port for the given scheme; if an alternative port is used, it MUST be explicitly specified by the application in question.

Registrations MAY also contain additional information, such as the syntax of additional path components, query strings, and/or fragment identifiers to be appended to the well-known URI, or protocol-specific details (e.g., HTTP [RFC7231] method handling).

Note that this specification defines neither how to determine the hostname to use to find the well-known URI for a particular application, nor the scope of the metadata discovered by dereferencing the well-known URI; both should be defined by the application itself.

Also, this specification does not define a format or media type for the resource located at "/.well-known/", and clients should not expect a resource to exist at that location.

Well-known URIs are rooted in the top of the path’s hierarchy; they are not well-known by definition in other parts of the path. For example, "/.well-known/example" is a well-known URI, whereas "/foo/.well-known/example" is not.

See also Section 4 for Security Considerations regarding well-known locations.

3.1. Registering Well-Known URIs

The "Well-Known URIs" registry is located at <https://www.iana.org/assignments/well-known-uris/>. Registration requests can be made by following the instructions located there or by sending an email to the <wellknown-uri-review@ietf.org> mailing list.

Registration requests consist of at least the following information:

URI suffix: The name requested for the well-known URI, relative to "/.well-known/"; e.g., "example".
4. Security Considerations

Applications minting new well-known URIs, as well as administrators deploying them, will need to consider several security-related issues, including (but not limited to) exposure of sensitive data, denial-of-service attacks (in addition to normal load issues), server
and client authentication, vulnerability to DNS rebinding attacks, and attacks where limited access to a server grants the ability to affect how well-known URIs are served.

[RFC3552] contains some examples of potential security considerations that may be relevant to application protocols and administrators deploying them.

4.1. Protecting Well-Known Resources

Because well-known locations effectively represent the entire origin, server operators should appropriately control the ability to write to them. This is especially true when more than one entity is co-located on the same origin. Even for origins that are controlled by and represent a single entity, due care should be taken to assure that write access to well-known locations is not granted unwittingly, either externally through server configuration or locally through implementation permissions (e.g., on a filesystem).

4.2. Interaction with Web Browsing

Applications using well-known URIs for "http" or "https" URLs need to be aware that well-known resources will be accessible to Web browsers, and therefore are able to be manipulated by content obtained from other parts of that origin. If an attacker is able to inject content (e.g., through a Cross-Site Scripting vulnerability), they will be able to make potentially arbitrary requests to the well-known resource.

HTTP and HTTPS also use origins as a security boundary for many other mechanisms, including (but not limited to) cookies [RFC6265], Web Storage [WEBSTORAGE], and various capabilities.

An application that defines well-known locations should not assume that it has sole access to these mechanisms or that it is the only application using the origin. Depending on the nature of the application, mitigations can include:

- Encrypting sensitive information
- Allowing flexibility in the use of identifiers (e.g., cookie names) to avoid collisions with other applications
- Using the ‘HttpOnly’ flag on cookies to assure that cookies are not exposed to browser scripting languages [RFC6265]
- Using the ‘Path’ parameter on cookies to assure that they are not available to other parts of the origin [RFC6265]
Using X-Content-Type-Options: nosniff [FETCH] to assure that content under attacker control can’t be coaxed into a form that is interpreted as active content by a Web browser

Other good practices include:

- Using an application-specific media type in the Content-Type header field, and requiring clients to fail if it is not used
- Using Content-Security-Policy [CSP] to constrain the capabilities of active content (such as HTML [HTML5]), thereby mitigating Cross-Site Scripting attacks
- Using Referrer-Policy [REFERRER-POLICY] to prevent sensitive data in URLs from being leaked in the Referer request header field
- Avoiding use of compression on any sensitive information (e.g., authentication tokens, passwords), as the scripting environment offered by Web browsers allows an attacker to repeatedly probe the compression space; if the attacker has access to the path of the communication, they can use this capability to recover that information.

4.3. Scoping Applications

This memo does not specify the scope of applicability for the information obtained from a well-known URI, and does not specify how to discover a well-known URI for a particular application.

Individual applications using this mechanism must define both aspects; if this is not specified, security issues can arise from implementation deviations and confusion about boundaries between applications.

Applying metadata discovered in a well-known URI to resources other than those co-located on the same origin risks administrative as well as security issues. For example, allowing "https://example.com/.well-known/example" to apply policy to "https://department.example.com", "https://www.example.com", or even "https://www.example.com:8000" assumes a relationship between hosts where there might be none, thereby giving control to a potential attacker.

Likewise, specifying that a well-known URI on a particular hostname is to be used to bootstrap a protocol can cause a large number of undesired requests. For example, if a well-known HTTPS URI is used to find policy about a separate service such as email, it can result
in a flood of requests to Web servers, even if they don’t implement the well-known URI. Such undesired requests can resemble a denial-of-service attack.

4.4. Hidden Capabilities

Applications using well-known locations should consider that some server administrators might be unaware of their existence (especially on operating systems that hide directories whose names begin with "."). This means that if an attacker has write access to the .well-known directory, they would be able to control its contents, possibly without the administrator realising it.

5. IANA Considerations

5.1. The Well-Known URI Registry

This specification updates the registration procedures for the "Well-Known URI" registry, first defined in [RFC5785]; see Section 3.1.

Well-known URIs are registered on the advice of one or more experts, with a Specification Required (using terminology from [RFC8126]).

The experts’ primary considerations in evaluating registration requests are:

- Conformance to the requirements in Section 3
- The availability and stability of the specifying document
- The considerations outlined in Section 4

IANA will direct the senders of any incoming registry requests to this document and, if defined, the processes established by the expert(s); typically, this will mean referring them to the registry Web page.

Per this document, IANA has:

- Updated the registration procedure to Specification Required.
- Added a "Status" column to the registry and marked all of the existing registrations as "permanent".
5.2. The Uniform Resource Identifier (URI) Schemes Registry

This specification adds a field to the registration template of the "Uniform Resource Identifier (URI) Schemes" registry, with the name "Well-Known URI Support" and a default value of "-".

If a URI scheme explicitly has been specified to use well-known URIs as per Section 3, the value changes to a reference to that specification. Initial values not equal to "-" are given in Table 1.

6.1. Normative References

6.2. Informative References

Appendix A. Frequently Asked Questions

Aren’t well-known locations bad for the Web?
They are, but for various reasons — both technical and social — they are sometimes necessary. This memo defines a "sandbox" for them, to reduce the risks of collision and to minimise the impact upon preexisting URIs on sites.

Why "/.well-known/"?
It’s short, descriptive, and according to search indices, not widely used.

What impact does this have on existing mechanisms, such as P3P and robots.txt?
None, until they choose to use this mechanism.

Why aren’t per-directory well-known locations defined?
Allowing every URI path segment to have a well-known location (e.g., "/images/.well-known") would increase the risks of colliding with a preexisting URI on a site, and generally these solutions are found not to scale well because they’re too "chatty".

Appendix B. Changes from RFC 5785

- Allowed non-Web well-known locations
- Adjusted IANA instructions
- Updated references
- Made various other clarifications
- Tracked supporting schemes in the "Uniform Resource Identifier (URI) Schemes" registry
